The Dutch system, however, is more elaborate than the U. S. Army system along the Mississippi River, as described by Mr. Buchanan. A preliminary dike called "spekdam" is thrown up on the seashore. Behind this dike a ditch, called "verskade sloot," is dug deep enough to drain the borrow-pits. The borrow-pits are separated by strips, left in place, to prevent erosive currents along the dike. The ditch is drained or pumped. Clay is placed and rolled in convex layers draining to both sides. In this manner no trouble is experienced in obtaining satisfactory clay dikes.

On the great rivers of Cochin-China[85] the outer slope (1 on 2) was provided with a clay cover, rolled with corrugated rollers. The inner slopes are 1 on 3.

In the course of time the ancient art of dike building has been greatly perfected in those countries that were in need of it. Higher profiles are needed in many places, however, as Mr. Buchanan shows for the Mississippi River. In Europe, thirty-nine major catastrophes have occurred since the Twelfth

Century. The problem remains to be able to predict maximum flood heights. The art of building leaves little to be desired; but the means of protection are much more intricate than the single lines of dike shown by Mr. Buchanan. An entire network of dikes exists in The Netherlands, forming auxiliary lines of defense. There are "sleeper" dikes, "bosom" dikes, inner and outer, winter and summer, river, and sea dikes. In many places slopes are protected in an elaborate manner.

The expedient of flattening slopes, which Mr. Buchanan describes, to make the structure stable in soft ground, is an ancient one. Caland, an experienced dike builder, writing in 1833,[83] describes the building of dikes on soil into which a stick could be thrust 12 ft without effort. He states that the side upthrust can be counteracted by flattening the slopes, and describes a case that occurred in Middelburg Harbor, in 1816. The Dutch have another ancient and successful method of constructing dikes on very soft foundations. It consists of covering the dike seat in the center by a "zink stuk," or sink piece of fascines. This prevents the lateral escape of the dike material, and of the foundation.

Doubtless the great differences in design in Europe and the United States are due to differences in local conditions. In the low countries of Europe, river engineering is a special trade, just as coal mining or weaving. Fascine work has been developed to a specialty. Dikes 40 or 50 ft high have been constructed between two submerged dikes of fascines, made of sink pieces. There is a great variety of methods of slope protection. In that manner the Dutch are able to construct clay and sand dikes through a depth of 25 or 30 ft of open sea, subject to the force of storms. Such methods would neither be possible nor economical in the United States where, apparently, an inordinate flattening of slope has been found to be the best solution.

The method of computing these slopes, described by Mr. Buchanan, does not seem to the writer to offer any better guaranty for their stability than that obtainable by older methods. Unfortunately, the great advances in soil mechanics are confined to the laboratory. The writer disagrees with Mr. Buchanan and feels that, for the present at least, the application of soil mechanics has caused no visible progress in: (1) The art of foundation design; and (2) the methods for computing soil stability. The first has always been quite adequate, and computation methods are as approximate as they ever were.

The practical art of constructing earthwork has been entirely successful since ancient times. Feeder dams on the Grand Canal in China, built 500 yr ago on alluvial soil, are still in use.[81] In the Indian Province of Madras alone there are 43 000 native earth dams used for storage reservoirs, of a total length of 30 000 miles (more than nine times the length of the Mississippi dikes) containing 200 000 separate masonry outlet works. One of these, the Madduk Masur Dike, has stored 800 000 acre-ft every monsoon for 400 yr.[87] The entire Netherlands has been diked since the Middle Ages. Entire cities containing the heaviest medieval towers stand on ancient pile foundations in soft soil below sea level. Among the many dams constructed on soil foundations[88] in modern times may be mentioned the Alcona Dam, built on a fine quicksand foundation 100 ft deep under artesian pressure, and successfully holding 40-ft head since 1923. None of these works needed the modern soils laboratory.

[88] *Transactions*, Am. Soc. C. E., Vol. 100 (1935), pp. 1303–1307.

That the computation methods are as approximate as they ever were is admitted by the foremost workers in this field. Thus, Prandtl[89] states that his theory on plastics is no longer applicable if stress changes with deformation (which condition generally prevails in soils). Professors Terzaghi and Froehlich[90] as late as 1936 admit that "the investigations perforce have the character of approximations for the purpose of obtaining a rough guess as to the settlement expected [writer's translation]."

Mr. Buchanan states that earth dikes on impervious strata can "now" be analyzed by methods such as the one developed by Glennon Gilboy, Assoc. M. Am. Soc. C. E.;[91] but it appears that in this, and in another, paper Professor Gilboy only applies the methods of Rebhahn[92] and Coulomb[93] and indeed specifically mentions that fact. In one of these two papers[94, 91] Professor Gilboy resorts to doing by trial and error what Coulomb did in 1821 by differentiation. The soils laboratory cannot be credited with developing ancient methods that have simply survived to the present time.

The efforts to compute soil stability date from 1764[95] and before. Since Moeller's book on earth pressures was published[96] nothing has been added which is any more serviceable than was stated therein. Retaining walls everywhere have been built with success by these theories; the 90-ft reinforced concrete retaining wall at the Junction Dam on a silt foundation[97] ranks among the highest examples.

Mr. Buchanan applies the method of Fellenius to the dike slope. Fellenius, in his book, "Erdstatische Berechnungen," attempts to introduce shear or cohesion and friction separately. The latest edition of Emperger's "Handbook for Reinforced Concrete" states that this leads to contradictions. The method referred to by Mr. Buchanan concerns circular shearing planes. Such shearing planes are already to be found in Coulomb's original treatise (1821).[93] Coulomb preferred the plane shear surfaces, considering the entire wedge-shaped sliding earth mass as one piece for the simple reason that it lends itself more readily to differential calculus. Fellenius, by using circles, has to resort to a trial-and-error process in order to obtain the conditions for a minimum stability; but Fellenius' method suffers from many more approximations than the Coulomb method. He attempts to divide the slope segment in vertical slices which are supposed to be subject only to the weight and the friction at the base of the corresponding strip. This is definitely a gross approximation as each strip is also subject to lateral pressure on both sides, with opposite directions of friction, which are not equal and cannot be omitted in a rigorous solution. The bases of Strips 8, 9, 10, and 11 (Mr. Buchanan's Fig. 8) are subjected to more pressure than merely the weight of the strips. Coulomb, therefore, preferred to regard the sliding mass as one piece. A sub-division into strips without considering lateral pressures is a rough approximation that does not approach closer to the truth. If the vertical pressure is unknown, a division of resistances into shear and friction is also not possible. Engineers, therefore, are as far from achieving an exact solution with Fellenius' method as they were with Coulomb's solution. No one can say which method gives closer results. In addition, a laborious trial-and-error method must be used to obtain results as open to question as ever.

The Dutch method of building dikes on very soft foundations, by means of a sink-piece in the center of the dike, utilizes the upthrust in the center to hold the sink-piece while preventing the downward movement on both sides of the center by means of the strength of the sink-piece. It is self-evident that computing the strength of the foundation merely by multiplying the depth of the clay foundation with the vertical load per square foot and dividing this by the allowable shearing stress, in order to obtain the base width of the dike, can be classified only as a rule-of-thumb. The actual conditions are far too complicated to be computed accurately by this means. The writer uses Rebhahn's method in such a case. The shear plane proposed by Mr. Haines as reported by Mr. Hough in Fig. 38 can conveniently be rectified into two straight lines joining in the perpendicular through the toe of the dike. The active pressures on one side must balance the passive pressures on the other and can easily be obtained graphically.

Soil mechanics, at least to the present, has not visibly enriched the "tool box" of the practicing engineer. Nevertheless, continued research remains of the greatest importance in spite of the paucity of practical results. A sober, critical examination finds recent enthusiastic reviews subject to considerable discount; but tests such as those described in 1923, in the very complete paper[98] by Jacob Feld, M. Am. Soc. C. E., will always be of great value.

SPENCER J. BUCHANAN,[99] Assoc. M. AM. Soc. C. E. (by letter).—The discussions contributed to this paper, both as regards the number and their contents, are gratifying to the writer and are indicative of the general interest in the use of the relatively new tool—soil mechanics—in solving unusual problems arising in connection with levee design. It is natural that some should disagree with the principles advanced.

It is the desire of the writer to add the name of Arthur Casagrande, Assoc. M. Am. Soc. C. E., as one who contributed much toward the development of the device, the details of which are shown in Fig. 6, for obtaining undisturbed samples of soil.

Mr. Knappen's comments regarding the levees in the Lower Mississippi Valley are most apropos. The writer concurs in the opinion that the general solution in so far as the design of levees in the Lower Mississippi Valley was sound at the time it was developed and used; also that much may be gained by giving consideration to the modifications indicated by recently acquired knowledge.

---

[98] *Transactions*, Am. Soc. C. E., Vol. LXXXVI (1923), p. 1448.

[99] Assoc. Engr., U. S. Waterways Experiment Station, Mississippi River Comm., Vicksburg, Miss.

Mr. Strohl's discussion regarding the application of soil mechanics to levee design and presentation of typical problems encountered in the Lower Mississippi Valley are noteworthy. The opinion voiced by the writer regarding the lack of development of seepage through a levee during a flood period is substantiated in the problem illustrated.

Mr. Creager's remarks regarding the limitations in space for a paper of this kind are appreciated. The design of levees, particularly in the Lower Mississippi Valley, involves consideration of practically every aspect advanced in the field of soil mechanics. Hence, to illustrate the general idea, very simple illustrations were used. It is true that in some instances the solutions of problems are not as simple and direct as indicated.

The restriction to mere mention of the effects of seepage forces on the design of slopes of levees or dams was deemed advisable inasmuch as at the time the paper was written, the writer felt (as indicated) that "further research" was needed. Some results are now available.

The stability of foundations as illustrated under the heading "The Design of a Levee Unit," is based on tests of specimens of the foundation medium in their undisturbed state. Effort is made to perform these tests so rapidly that no consolidation of the specimen occurs. Thus, the design is based not on the ultimate shearing strength that may eventually be developed upon complete consolidation, but upon the actual strength, in place, as nearly as may be ascertained.

The opportunity for full-scale research such as that mentioned by Mr. Feld is appreciated. However, as he states, it will be some time before the results of such studies can be reported. Much stress, of course, must be placed on field observations of full-scale structures as well as on a thorough investigation in the laboratory. Thus, the engineer should not veer to the "right" or to the "left" but follow a straight course. Mr. Feld is correct in stating that the surface of rupture developed during the failure of a slope is not always a cylindrical surface. However, it is the understanding of the writer, from discussion of this phenomenon with field engineers who have observed numerous such failures in the levees along the Lower Mississippi Valley, that cylindrical surfaces of rupture for these structures can be taken as typical. Each problem of this type must be considered separately. Attention is invited to the fact that the illustration regarding the design of a levee, in so far as the foundation is concerned, conforms closely with the basic assumptions as indicated by Mr. Jürgenson in his paper.[7]

Mr. Chang's presentation of the difficulties experienced in the use of loess for the levees in China is worthy of note. No complications have arisen in connection with the structure illustrated by Fig. 4 which is formed of loess.

The wealth of information contributed by Mr. Senour in his discussion of the design, construction, and maintenance of levees is most interesting. The writer concurs in the remark, "Experience is invaluable, of course but unless it is supplemented with a knowledge of the underlying principles that govern soil behavior, experience is distinctly at a disadvantage when it becomes necessary to design in a field not covered by prior operations." It is a thought that deserves serious consideration, particularly by those who maintain a pessimistic attitude regarding soil mechanics. Mr. Senour's descriptions of the equipment used for the construction of levees along the Lower Mississippi River should explain to many the difference in the design between the structures considered in the paper and those built elsewhere, particularly those constructed abroad. A hand-made levee, as compared with those constructed by machines of large capacity, would naturally result in structures different to some extent in shape and design.

Professor Taylor's treatment of the effect of seepage on the stability of side slopes, although it is only an approximate method for simple embankments, appears to be sound and meritorious. The statement following Fig. 3 concerning the force, F_f, is correct.

Mr. Wells' brief discussion of his observations of levees in various localities is interesting. The method of designing side slopes mentioned, as advanced by Professor Taylor, was not available at the time this paper was prepared. The writer concurs in the statement that this new method is an improvement over the graphical procedure. The basic paper appears to have served well one of the purposes intended by the writer in that it has brought into the open a discussion of general features such as those presented by Mr. Wells. Mr. Wells' comments regarding the plan of providing land-side drainage to assist in the solution of the problem of "sand boils" are worthy of consideration.

Mr. Streiff's comments are interesting in that they show how others have attacked the problem of levee design. It is natural that there should be considerable difference in the designs of levees in different parts of the world. Unfortunately, no information was given regarding the materials used and conditions encountered abroad. The writer does not agree with Mr. Streiff in his statement "for the present, at least, the application of soil mechanics has caused no visible progress." The interest manifested by the Engineering Profession both in the United States and abroad, involving foundations and structural stability of soils, appears more than to substantiate the writer's general attitude as expressed in the basic paper.

STANLEY M. DORE,[100] M. AM. SOC. C. E. (by letter).—The rating of soil grading curves or mechanical analysis curves into groups is particularly useful in connection with foundation or borrow-pit investigations and explorations. The method of rating described by Professor Burmister in his discussion of this Symposium and also in his discussion[101] of the paper by Frank B. Campbell, Assoc. M., Am. Soc. C. E., is similar in many respects to the Kendorco classification previously described[102] and later revised in the manner shown in Fig. 72 to include more classes of finer materials. The Kendorco system seems more simple, easier to apply, and more easily understood and used by engineers who are not soil laboratory technicians. Its usefulness has been tried under practical construction conditions by the Massachusetts Metropolitan District Water Supply Commission and by the Board of Water Supply of New York City.

[102] "Permeability Determinations, Quabbin Dams," by Stanley M. Dore, M. Am. Soc. C. E., *Transactions*, Am. Soc. C. E., Vol. 102 (1937), p. 690, Fig. 5.

A modification of this system has also been used by the U. S. Army Engineers in connection with their studies of flood-control dams and dikes for the Connecticut River and this modification was described in a discussion[103] of Mr. Campbell's paper by Frank E. Fahlquist, Assoc. M. Am. Soc. C. E., and Mr. Waldo I. Kenerson.

The use of mechanical analysis curves of borrow-pit materials for estimating the yield of core material that will occur in a hydraulic-fill embankment when that borrow-pit material is being used, has been made by the writer in a manner similar to that suggested by Professor Burmister. The writer has noted, however, that there may be a marked difference in the yield of core materials actually obtained in construction from that theoretically indicated by the use of the mechanical analysis curves in the manner suggested by Professor Burmister. Relatively large quantities of finer materials are trapped in the beaches and in the volumes between the beaches and the core. The theoretical estimate makes no allowance for this condition. Usually, the porosities of the core material are radically different from those of the borrow-pit materials, although, in many cases, the porosities in the beaches may not be dissimilar. In making any quantitative estimate, proper allowances for these differences in porosities must be considered. For these reasons, the writer does not accept the yield values given by Professor Burmister, for various hydraulic-fill dams, as correct. They represent neither yield in percentages by weight nor yield in

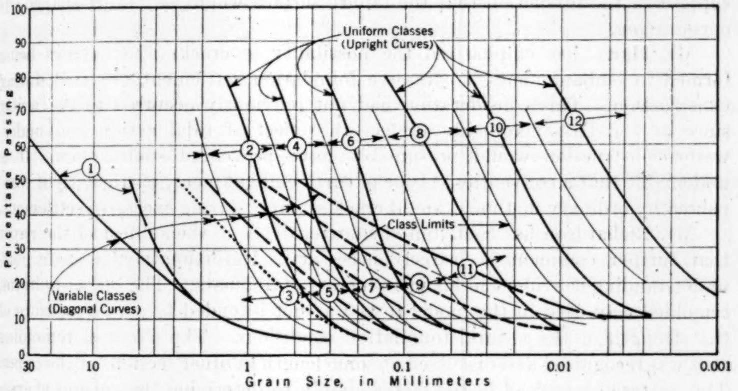

FIG. 72.—KENDORCO CLASSIFICATION

---

[103] *Proceedings,* Am. Soc. C. E., May, 1938, p. 998.

percentages by volume, unless the volume of fines trapped in the beaches and elsewhere offsets the increase in volumes due to differences in porosities.

On the other hand, in the sluicing bin test, actual construction conditions are reproduced so that the yield results obtained should be representative.

The writer is in accord with many of the ideas expressed in Professor Burmister's discussion, in that the grading or the mechanical analysis curves can be used more widely to estimate, in advance, the quantity and quality of embankment construction to be expected, using certain borrow-pit materials.

BENJAMIN K. HOUGH, JR.,[104] ASSOC. M. AM. SOC. C. E. (by letter).—The several discussers of the paper have been helpful in making many valuable contributions to the subject. Dean Hollister has emphasized the gain in stability resulting from contact of the embankment with the rock surface underlying the plastic zone after complete displacement of the clay. His support of the prediction that the failure surface would be "heart-shaped" is encouraging.

Mr. Harza has emphasized the possibility of cracks and cavities being formed in embankments if excessive foundation settlement occurred during construction. This consideration had not previously occurred to the writer since at the Passamaquoddy project the effect of tidal action and underwater construction would presumably have prevented such action. It is undeniable that a conventional type of earth embankment, particularly if compacted by ordinary methods, would crack severely during excessive settlement.

Mr. Richardson has contributed so extensively to the subject of the paper that further comment is scarcely necessary. Unfortunately, a slight misunderstanding is evident in his introductory statements. The bed of uniform, remolded clay used in the model tests was not intended to give a measure of the strength of the natural foundation conditions. The effect of remolding clay was recognized and discussed at some length in other sections of the paper. This material was used in the model simply to determine the general characteristics of the failure surface or zone. Only qualitative results from the model studies were expected or obtained. Stress analysis was conducted analytically later with the model results as a guide.

Mr. Richardson's presentation of a method of stress determination based on the theory of elasticity is of considerable general value and interest, but the writer feels that in its present form it could not have been applied to the particular problem discussed in the paper. This problem was: (1) To design a section with sufficient base width to insure against foundation failure; (2) to determine how far an alternate, very steep-sided section would penetrate into the foundation as a result of foundation failure; and (3) to make an economic study of the initial and the alternate designs to determine their relative costs. For the first part of the problem, a method such as that described by Mr. Richardson could well have been utilized providing the effect of the rock surface or "rigid boundary" had been considered as it is in methods described by Messrs. Middlebrooks and Jürgenson. In the second part of the problem, the writer believes that these methods could not have been used at all.

---

[104] Engr., U. S. Engr. Office, Ithaca, N. Y.

The apparent lack of suitable methods for determining settlement of embankments as a result of foundation failure was the primary reason for developing the Haines method.

The suggestion of Mr. Richardson that artificial mud waves be placed in the early stages of construction as a stabilizing expedient to prevent subsequent embankment settlement is noteworthy. This procedure might be adequate in certain cases but in the case of the Eastport (Me.) structures the initial sections (designed to prevent foundation failure) had base widths extending far beyond the mud waves anticipated for the alternate sections; and in these alternate sections final stability was dependent not only on the counterbalancing effect of the mud waves but also on displacement of soft clay by the much more stable embankment fill material, and decrease of the depth of the plastic layer. In some cases, computations indicated that this displacement would be so extensive as to result in penetration of fill material all the way to rock.

Mr. Creager has presented an argument, relative particularly to design by photo-elastic model studies, which should be given serious consideration in all future work of this nature. It is true that in these model studies, and in analysis by theories of elasticity, it is generally assumed either that embankment loads are transmitted entirely to the soil skeleton without regard to the pore water, or that a certain percentage of the load is transmitted to the soil and the remainder to the pore water; but in this latter case, insufficient consideration has been given to the direction in which the hydrostatic forces are dissipated. Analysis of the water forces at this time appears to be extremely complicated. However, it is felt that this consideration is an important one, not to be dismissed with the assumption that such forces are negligible, and it is hoped that Mr. Creager will continue his efforts toward developing a solution for this problem.

The writer takes issue with certain of the statements made by Mr. Feld in the paragraph which he devoted to the discussion of the writer's paper. There seems to be no justification for his statement that the impervious blanket, to be added after construction of the rock-fill, is of "much greater weight than the rock-fill section." Fig. 73 shows the relative proportions of blanket and rock-fill as considered in the studies reported in the paper. It is not denied that addition of the blanket would affect stability conditions, but this effect was analyzed and found to be insufficient to displace the rock-fill after the completion of its construction. The writer appreciates Mr. Feld's reference to the foundation treatment termed "floating foundation," consisting of fine

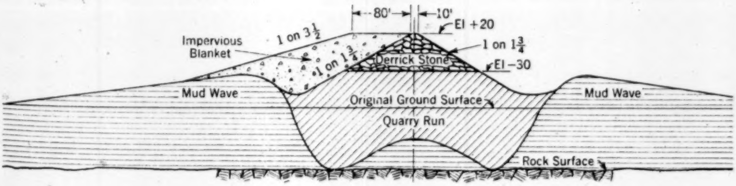

FIG. 73.

sand pumped into place. It is acknowledged that this should prove to be valuable in such applications as were discussed by the footnote references. The writer's studies, however, indicated that it would have been entirely inadequate in the case of the Eastport structures. In comparing the writer's conclusions with those of Mr. Feld, it is important to note that the foundation data available to the latter were limited to the results of a few, essentially unreliable wash-borings, whereas the writer had access to data from an extensive program of undisturbed sampling and a complete series of laboratory tests.

In preparing this final discussion the writer was fortunate in having had the assistance of Mr. Haines who was largely responsible for developing the method to which his name has been given. It is believed by both Mr. Haines and the writer that the problem discussed in the paper requires extensive additional study, and it is hoped that supplementary methods of analysis will be developed in the near future.

DESIGN OF REINFORCED CONCRETE IN TORSION

BY PAUL ANDERSEN,[1] ASSOC. M. AM. SOC. C. E.

WITH DISCUSSION BY MESSRS. C. W. DEANS, L. E. GRINTER, BRUCE G. JOHNSTON, DEAN PEABODY, JR., WALTER H. WHEELER, A. FLORIS, E. NEIL W. LANE, A. A. EREMIN, HAROLD E. WESSMAN, AND PAUL ANDERSEN

SYNOPSIS

In analyzing space structures torsional moments may be readily determined by the method of successive approximations.[2] For a given torsional moment an economical section is the square. If it is reinforced with 45° spirals such a section lends itself to mathematical investigation and a rational design procedure can be developed. The percentage of reinforcement in a rectangular section can also be approximated. For convenience of reference, a complete list of the letter symbols used in this paper is given in the Appendix.

DISTRIBUTION OF TORSIONAL MOMENTS

That the method of moment distribution can be applied to space structures[2] has been demonstrated by Hardy Cross, and N. D. Morgan, Members, Am. Soc. C. E. In order to find torsional moments in a three-dimensional frame it is necessary to supplement the "flexural" beam constants with "torsional" beam constants. Torsional stiffness is the moment which, applied at one end of a member, will produce unit rotation at this end, while the other end is fixed. It follows that the torsional stiffness of a member of length, L, is:

$$K_T = \frac{E_s\,T}{L} \quad \text{(1)}$$

in which E_s = the modulus of elasticity in shear; and T = the torsion factor which, for a circular section, is the polar moment of inertia and for a rectangular section, approximately:

$$T = \frac{b^3\,d^3}{3.58\,(b^2 + d^2)} \quad \text{(2)}$$

NOTE.—Published in October, 1937, *Proceedings*.

[1] Asst. Prof. of Structural Eng., Univ. of Minnesota, Minneapolis, Minn.

[2] "Continuous Frames of Reinforced Concrete," by Hardy Cross and N. D. Morgan, Members, Am. Soc. C. E., John Wiley & Sons, N. Y., 1932, p. 117.

b being the width, and d, the depth of the member. The torsional carry-over factor is the ratio of $\frac{M_1}{M}$, in which M is an arbitrary moment applied at one end of the member, which is assumed as free to rotate, and M_1 is the resisting moment at the other end of the member, which is assumed as fixed against rotation. These two moments, of course, are always equal, and, therefore, the torsional carry-over factor is always unity.

Fixed end torsional moments are directly proportional to the distance from the point of application of the external moment to the opposite support. Thus, for a beam with a constant moment of inertia, the fixed end torsional moments are,

$$M_f = M \frac{n}{m + n} \qquad \text{(3a)}$$

and

$$M_t = M \frac{m}{m + n} \qquad \text{(3b)}$$

in which m and n are the distances from the applied moment to the fixed ends, respectively. If members subjected to torsion join members in flexure, the flexural stiffnesses of the latter are expressed by,

$$K_F = \frac{4\,E\,I}{L} \qquad \text{(4)}$$

If

$$E_s = \frac{E}{2.25} \qquad \text{(5)}$$

is substituted in Equation (1), the corresponding torsional stiffness of a member becomes,

$$K_T = \frac{E\,T}{2.25\,L} = E \times \frac{1}{L} \times \frac{b^3\,d^3}{2.25 \times 3.58 \times (d^2+b^2)} \qquad \text{(6)}$$

If the relative stiffness of a member in flexure is expressed by $\frac{I}{L}$, the relative torsional stiffness will be $0.031 \times \frac{I}{L} \times \frac{b^3\,d^3}{b^2 + d^2}$.

The example in Table 1 will illustrate the procedure for distributing moments in a space structure due to an eccentrically loaded beam. The problem is conveniently solved by considering first the effects of the direct load on the center beam as in Table 1(a), and then the moments due to the torsional moment as in Table 1(b). For the sake of simplicity, side-sway is neglected even if there is some side-sway present, due to the eccentric load of 150 kips in Example (a), Table 1, deflecting Points A and A'. It is customary, in plane structures, to stop the process of moment distribution after a distribution, since the sum of the moments around a joint should equal zero. However, in a space structure this will not make the torsional moments in the members balance and the torsional moments (external and internal) in any one member should balance. It is just as correct, of course, to stop after having distributed the flexural moments as after having balanced the torsional moments. If the process is carried to the proper number of distributions it may be stopped after either, as the error would be insignificant.

It should be noted that the flexural and torsional moments in Table 1 can also be found by the slope-deflection method. The unknowns will be the rotations of Points A and A' in the two perpendicular planes; this makes a total of four rotations, which can be determined from the four equations expressing the condition that the two sets of moments at each joint, A and A', must balance.

* *T* = torsion; *F* = flexure.

SHEARING STRESSES

The maximum unit torsional shearing stress in a rectangular section subjected to a torsional moment, M, is approximately,

$$v_m = \frac{M}{b\,d^2}\left(1.8 + \frac{3 \times d}{b}\right) \ldots\ldots\ldots\ldots\ldots\ldots (7)$$

For a given cross-sectional area this stress (which occurs at the middle of the long side, d) is a minimum when $b = d$; in this case it can be expressed by,

$$v_m = \frac{24\,M}{5\,b^3} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (8)$$

For a rectangular section, the maximum unit vertical shearing stress due to a total vertical shear, V, equals,

$$v_m' = \frac{3}{2} \times \frac{V}{b\,d} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (9)$$

and is dependent on the area of the rectangle.

As a rule, the bending moments that accompany heavy shears and torsional moments are comparatively small. The designer of concrete in torsion, therefore, is interested primarily in square sections or in sections that are nearly square. It should be noted that, in some cases, the beam that has a width greater than its depth may be still more economical than the square, because its maximum torsional shearing stress occurs where the vertical shearing stress is zero.

Reinforced Concrete in Torsion

If a circular concrete section, reinforced by a 45° spiral (Fig. 1), is subjected to torsion, and it is assumed that this reinforcement takes all tensile stresses greater than the permissible tension for plain concrete, it can be shown that the following relation exists[3]:

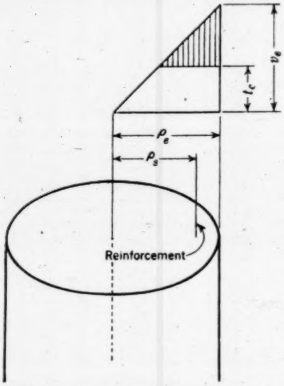

FIG. 1

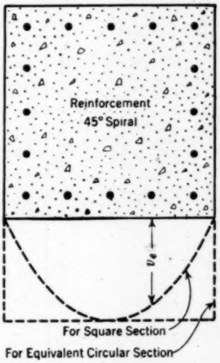

FIG. 2

$$N A_s = (v_e - s_c)^2 (3\,v_e^2 + 2\,v_e\,s_c + s_c^2)\,\frac{\pi \rho_e^3 \sqrt{2}}{12\,v_e^3\,\rho_s\,s_s} \qquad (10)$$

and for a square section (Fig. 2),

$$F\,N\,A_s = (v_e - s_c)^2 (3\,v_e^2 + 2\,v_e\,s_c + s_c^2)\,\frac{\pi \rho_e^3 \sqrt{2}}{12\,v_e^3\,\rho_s\,s_s} \qquad (11)$$

in which, N = number of bars, 45° to the axis, cut by a horizontal plane; v_e = shearing stress along the edge of a cylinder, produced by a twisting moment, M; s_c = permissible unit tensile stress for concrete; ρ_e = radial distance in a horizontal cutting plane, measured from the axis of a cylinder to the edge; ρ_s = radial distance to the steel reinforcement; s_s = permissible unit tensile stress for steel; and F = a reinforcement efficiency coefficient relating to the variation in tensile stress along the edge. The coefficient, F, is always less than one and will approach $F = \frac{2}{3}$ as the pitch of the spiral decreases, this being the ratio between the area of the parabola representing the variation of shearing stresses along the edge and the area of the rectangle expressing uniform tensile stress in all the steel rods of the spiral.

---

[3] "Experiments with Concrete in Torsion," by Paul Andersen, *Transactions*, Am. Soc. C. E., Vol. 100 (1935), p. 949.

If c is the perimeter of the spiral and p the pitch, it is seen that,

$$N = \frac{c}{p\sqrt{2}} = \frac{8\,\rho_s}{p\sqrt{2}} \qquad (12)$$

With $F = \frac{2}{3}$, substitute Equation (12) in Equation (11) and transpose:

$$\frac{A_s}{p} = (v_e - s_c)^2(3\,v_e^2 + 2\,v_e\,s_c + s_c^2)\,\frac{\pi\rho_e^3}{32\,v_e^3\rho_s^2 s_s} \qquad (13)$$

For a given square subjected to a known torsional moment all quantities in Equation (13) are known except A_s, the cross-sectional area of one spiral rod, and p, the pitch of the spiral. The designer has the choice of selecting either one of these unknowns and then to find the corresponding value of the other.

The design of a reinforced concrete beam in torsion is shown in Fig. 3, in which the main reinforcement consists of five 1-in. round bars, top and bottom; the vertical stirrups, $\frac{1}{2}$-in. round bars; and the spirals, $\frac{1}{4}$-in. round bars. The maximum torsional moment in the beam occurs when the eccentric load on the beam is close to the column; the moment distribution for this case is indicated in Table 2. It should be noted that whereas the maximum vertical shear along the beam varies according to a curved line the maximum torsional moment will vary as a straight line.

The maximum vertical shearing stress is $v_m' = \frac{60\,000}{\frac{7}{8} \times 24 \times 21} = 136$ lb per sq in.; and the maximum torsional shearing stress is, $v_m = \frac{3 \times 400\,000}{5 \times 12^3} = 139$ lb per sq in.

The beam should be designed first for vertical shear, adopting a lower allowable stress in the concrete, and then for torsion. Suppose that the total allowable shearing stress for concrete without web reinforcement is 90 lb per sq in.; it is now assumed that this stress can be divided into two parts in proportion to the magnitudes of the vertical and torsional shearing stresses: Of the vertical shear the concrete takes $\frac{136}{275} \times 90 = 44$ lb per sq in.; and, of the torsional shear, it takes $\frac{139}{275} \times 90 = 46$ lb per sq in. Applying Equation (13) to the part of the beam adjacent to the column support gives,

$$\frac{A_s}{p} = (139\text{–}46)^2(3 \times 139^2 + 2 \times 139 \times 46 + 46^2)$$

$$\times \frac{\pi \times 12^3}{32 \times 139^3 \times 10^2 \times 16\,000} = 0.0249$$

Using $\frac{1}{4}$-in. round rods for the spiral gives, $p = 1.97$ in.

A $2\frac{1}{2}$-in. horizontal spacing, as indicated on Fig. 3, will give a pitch somewhat less than required and, therefore, is on the safe side. Equation (13) is now used to compute the pitch, p, at the quarter-points and mid-span.

FIG. 3

THE RECTANGULAR SECTION

In the case of a rectangular section, A. A. Eremin, Assoc. M. Am. Soc. C. E., has suggested the use of formulas developed by the writer in 1934[4] with the exception that the value of ρ_e be taken as,

---

[4] *Transactions*, Am. Soc. C. E., Vol. 99 (1934), p. 980.

$$\rho_e' = \sqrt[3]{\frac{2\,b^2 d}{\pi\left(3 + \dfrac{2.6}{0.45 + \dfrac{d}{b}}\right)}} \quad \text{.....................} (14)$$

in which ρ_e' = the radius of a circular section equivalent in strength to a rectangular section. To ρ_s (the distance from the center of the section to the spiral reinforcement) should be assigned the value of ρ_e' less the distance from the center of the spiral to the outside of the beam. The efficiency coefficient should also be somewhat reduced; in view of the lack of experimental data for rectangular sections, however, the writer suggests that the value of two-thirds be used also for rectangular beams, and that the same weight of spiral steel be placed on all four sides.

It would appear that in a rectangular section, designed in this manner, the reinforcement would be over-stressed along the center of the long side and under-stressed along the center of the short side. To the writer, however, it seems a reasonable assumption that, to some extent, the presence of equal quantities of spiral steel in both sides will re-distribute the shearing stresses to the advantage of the long side. For rectangular sections nearly square $\left(\frac{d}{b} \underset{<}{\equiv} 1.25\right)$, the writer believes the method outlined to be safe.

CONCLUSIONS

The paper outlines the various steps in the design of reinforced concrete in torsion. The Cross method provides a useful tool for determining torsional moments in a space structure.

The square section, which is a good torsion shape, can be reinforced effectively against torsional stresses by the 45° spiral. The quantity of reinforcement can be found by a procedure similar to the accepted practice for designing web reinforcement for vertical shear. This procedure can also be followed for rectangular beams.

APPENDIX

NOTATION

The following symbols, introduced in the paper, conform essentially with "Symbols for Mechanics, Structural Engineering, and Testing Materials" compiled by a Committee of the American Standards Association, with Society representation, and approved by the Association in 1932[5]:

A = area; A_s = cross-section area of steel bars;
b = breadth, or the short side of a rectangular section;
c = perimeter of a spiral;
d = depth, or the long side of a rectangular section;
E = modulus of elasticity; E_s = modulus of elasticity in shear;
F = a reinforcement efficiency factor that allows for surface tension taken by reinforcement;
I = moment of inertia;
K = stiffness; K_F = flexural stiffness; K_T = torsional stiffness;
L = length of a member;
M = bending moment; an arbitrary moment applied at one end of a member; M_f = fixed-end moment; M_t = torsional moment;
m = a distance from the fixed end of a beam (see, also, n)
N = number of bars, 45° to the axis, cut by a horizontal plane;
n = a distance from the fixed end of a beam (see, also, m);
p = pitch of a spiral;
s = unit stress; s_c = permissible unit tensile stress for concrete; s_s = permissive unit tensile stress for steel;

---

[5] A. S. A.—Z10a—1932.

T = torsion factor = polar moment of inertia in a circular section;
V = total vertical shear;
v = unit shearing stress; v_m = maximum shearing stress; v_m' = maximum unit vertical shearing stress; v_e = shearing stress along the edge of a cylinder, produced by a twisting moment, M;
ρ = radial distance in a horizontal cutting plane, measured from the axis of a cylinder: ρ_e = radius to the edge; ρ_s = radial distance to the steel reinforcement; ρ' = radius of a circular section, equivalent in strength to a rectangular section.

DISCUSSION

C. W. Deans,[6] Esq. (by letter).—The interesting method presented by Professor Andersen is rational, and the resulting designs appear to be safe. The material in Table 2 could be presented in such a manner that the final results are found more readily by inspection. Table 3 demonstrates the writer's suggestion. The lines underscoring the balancing moments indicate that the joint moments are balanced at this stage. If the individual carry-over moments (see "C. M." in Table 3) are recorded as shown, the total unbalanced moments that are ready for distribution at each step are apparent. In the example solved, the moments in members meeting at Joints u and v are identical to corresponding members meeting at Joints x and y, respectively, and can be omitted.

* S. R. = stiffness ratio; C. F. = carry-over factor; F. M. = fixed-end moment; D. = distribution; and, C. M. = carry-over moment. † See author's Fig. 3(*c*).

Attention should be called to Equation (12), in which p is defined, simply, as the pitch. It should be made clear that this is the value of the pitch at right angles to the spiral bars and not the distance between bars measured parallel to the axis of the spiral. The writer had some difficulty in checking the formula until he recognized this fact.

L. E. Grinter,[7] M. Am. Soc. C. E. (by letter).—The thought of studying a continuous framed structure as a space problem may seem a great refinement that strains all practical conceptions of design. However, the writer takes the position that no refinement of analysis is wasted that clarifies the picture of the action of the structure. Certainly it is a serious crudity to neglect entirely the torsional resistances of large beams and girders in the design of continuous frames. Whether a full space-frame study can be justified will depend largely upon the relative flexural and torsional resistances of the various members.

---

[7] Director of Civ. Eng., and Dean, Graduate Div., Armour Inst. of Technology, Chicago, Ill.

Distribution Factors.—The stiffness factor is proportional to $\frac{E\,I}{L}$ for a beam, whereas this factor is $\frac{E_s\,J}{L}$ for a circular torsional section, J, of course, being the polar moment of inertia. In this form the comparison is evident although the latter expression can be determined readily from an elementary study of virtual work. Since $\theta = \int \frac{T\,t'\,ds}{E_s\,J}$ and since both T and t', the real and virtual torque moments, will be constant and equal to unity, $\theta = \frac{L}{E_s\,J}$; and $\frac{1}{\theta}$, the stiffness factor, becomes $\frac{E_s\,J}{L}$. Obviously, the carry-over factor is unity since a torsional moment passes from one end to the other of a member without reduction.

Signs of Moments.—Several sign conventions would be possible in the study of continuity in space frames. However, there seems little justification in this case for any convention other than the one introduced by the writer for balancing moments in planar frames.[8] Although a sign convention based on fiber stresses (cantilever moment negative) may serve adequately for continuous beams and even passably for planar frames, it is fundamentally unsound for the study of space structures because of its inapplicability to torsional problems. The basic sign convention should be that a positive moment (either flexural moment or torque moment) is one which tends to rotate the adjacent joint clockwise. Fig. 4 illustrates this sign convention applied to torque moments.

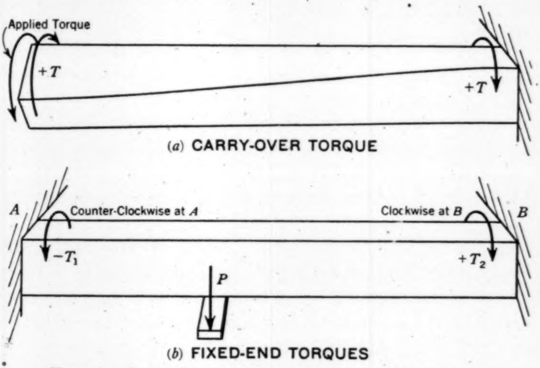

FIG. 4.—SIGN CONVENTION FOR TORQUE MOMENTS.

The sign of the carry-over factor based on the foregoing sign convention has the usual positive value for moment distribution. Furthermore, a positive torque moment must also be carried over with the same positive sign (see Fig. 4(*a*)). Hence, the common carry-over factor for bending moment, which is + 0.5, becomes + 1.0 for torque moment. The entire sign convention for planar frames, therefore, remains unchanged for solving space frames. No confusion is possible if one always considers only the action of the member on the joint, which is the fundamental conception used in classical truss analysis by the graphical method.

---

[8] *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 14.

Fixed-End Torque Moments.—As the author mentions, when an internal torque moment is applied, the fixed-end torque moments are supposed to be inversely proportional to the relative distances to the two ends of the member. For instance, if a torque moment, T, is applied to the member, AB, as shown in Fig. 5, the larger resisting moment occurs at the near end, A, and is equal to,

$$M = T\left(\frac{b}{a+b}\right) \qquad \text{(15)}$$

This will be evident from the fact that the rotation over the length, a, must be equal to the rotation over the length, b. Since the rotation is proportional to the acting torque moment and to the length, the relation expressed in Equation (15) follows for a homogeneous beam. For a haunched beam or one in which the torsional resistance is influenced by the addition of much steel for shear resistance, this simple relationship does not hold. Approximate fixed-end torque moments for a haunched beam might still be found by an integration. The writer calls attention to the fact that such fixed-end torque moments must be accepted as approximate since the action of vertical or diagonal shear reinforcement for torsional resistance is not predictable with mathematical accuracy. It is worth mention that torsional resistance or stiffness for reinforced concrete depends very largely upon the resistance of stirrups, the most unpredictable quantity in the analysis of reinforced concrete. In contrast, the flexural resistance or stiffness of a beam is dependent principally upon the action of tension steel, the most predictable factor in the analysis of reinforced concrete.

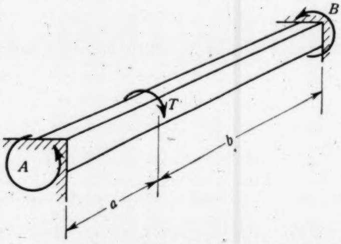

Fig. 5.—Fixed-End Torque Moments.

Arrangement of Computations.—The author appears to favor the use of tabulated coefficients for his analysis. More than a decade of experience with the method of balancing moments and with numerous similar balancing procedures seems to have convinced the originator of the method[9] and others who have used it widely, that such tabulation leads to no benefit. In fact, it eliminates the major reason for the choice of the method of balancing moments; that is, the close connection between the action of the structure and the arithmetic procedure of the computations. The use of a table of moments leads to a purely routine procedure and divorces the computations from the possibility of their interpretation as successive causes of the structural action. Fig. 6 was prepared to show the simplicity of arrangement of the computations at their proper places on a line perspective of the structure.

---

[9] "Analysis of Continuous Frames by Distributing Fixed-End Moments," by Hardy Cross, M. Am. Soc. C. E., *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 5.

These computations also illustrate the desirability of combining torque and flexural moments into one analysis although they must be entered in the separate groups designated in Fig. 6 as *T* and *F*. The writer's preference for this attack is simply that it is not possible to divorce these separate actions anyway because a flexural moment can turn into a torque moment in passing around a corner. Since torque cannot be studied separately from flexure in space frames, there seems little reason to separate the terms in the manner suggested by the author. The final point to notice in Fig. 6 is the separation of the flexural moments in the columns under the heading of *F* and *F′*. This designation is used to indicate that these flexural moments act in different planes and, hence, must be applied individually in design.

Accuracy in Balancing Moments.—It will be noticed that the final moments computed in Fig. 6 do not check exactly with those shown by the author in Table 1. It is of no moment which solution is more nearly exact since either would be more accurate than the standard tools of internal stress analysis for reinforced concrete sections. For instance, one flexural moment is computed as 75 kip-ft by the author and as 77 kip-ft by the writer. The variation of 3% is about the standard of accuracy that the writer considers desirable for the analysis of concrete framed structures. Naturally, it is understood that this value does not represent the probable inaccuracy inherent in any attempt to predict the true stresses in the actual structure.

FIG. 6.—BALANCING MOMENTS FOR A SPACE FRAME.

Resistance of Reinforced Concrete in Torsion.—The author has clarified the necessary constants for investigating the stresses in a rectangular reinforced concrete section under torsion. This analysis is subject at least to the same questioning that in the past has been directed to the analysis of reinforced concrete beams. Actually, one should feel some question about the use of Equations (6) to (14) until tests have justified the author's procedure in the same manner that they have justified the ordinary theory of reinforced concrete beams. However, it is natural and proper that theory should precede full confirmation by tests.

One interesting feature of the design of a reinforced concrete crane girder for torsion, as indicated by the author, is the use of continuous diagonal stirrups. Since vertical stirrups and horizontal rods have been found quite adequate for resisting diagonal tension resulting from shear and flexure, there would seem to be no necessity for changing this proved and simple device when torsion is present. Failure is still by diagonal tension. The design criterion should still be to space hoops of any type in such a manner that every crack must cross at least one shear bar which itself is anchored adequately. The slope of the bar is less important than its area and anchorage.

Conclusion.—The author has served the profession by collecting in one paper many data on the analysis and design of reinforced concrete space frames, in which torsion is almost inevitably present. Perhaps this excellent paper may help convice designers that it is not too difficult, or at least not impossible, to design a building frame as a space structure.

Bruce G. Johnston,[10] Assoc. M. Am. Soc. C. E. (by letter).—Nearly all structural frames of the so-called "rigid" type are space frames; few are analyzed as such. In many cases there is little interaction between the various planes of the structure, and the analysis may be satisfactorily divided into separate plane problems. In frames of the type represented by the author, however, the three-dimensional analysis is essential because of the torsion introduced. In actual design direct torsional loads should be avoided wherever practicable.

Three general types of deflection occur in a member of a "rigid" frame—it can be bent, twisted, or deformed longitudinally. A complete analysis of such a statically indeterminate structure would include the effects of these three types of deflection. Only in "hybrid"[11] structures, or in structures of unusual proportions, does it become necessary to consider the effect on the analysis of the secondary interaction of two, or possibly all three, types of deflection. The effect on the design, or total deflection, may be another matter. The author has presented, in an orderly manner, the application of the Cross method of moment distribution to the analysis of the combined bending and twisting problem.

The writer wishes to point out certain variations which occur in extending the author's method to beams of non-uniform cross-section, or to cases in which structural steel beams are used instead of reinforced concrete. It is first necessary to discuss the basic torsion constant, denoted by the symbol, T, in the paper. In 1855, Saint Venant presented the solution of the torsion of a prism of rectangular cross-section.[12] In Fig. 7 the writer has shown the deviation of Equation (2) for the torsion constant from the solution of Saint Venant. It is seen that this formula is most nearly correct for the square section, and that an error of only 6% or less is introduced for ratios of long to short side as great as 4. If the ratio of the long to the short side is 1.6, or greater, as is the usual case for beams designed primarily for bending, another simple formula gives a closer approximation than Equation (2):

---

[10] Asst. Prof. and Asst. Director, Fritz Eng. Laboratory, Lehigh Univ., Bethlehem, Pa.

[11] See "The Relation of Analysis to Structural Design," by Hardy Cross, M. Am. Soc. C. E., *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 1931.

$$T = \frac{b^3 d}{3}\left(1 - 0.63\,\frac{b}{d}\right) \dots\dots\dots\dots\dots\dots (16)$$

The deviation of Equation (16) from the correct solution is also shown in Fig. 7. The greatest error is for the square section (about 12.3%) but it decreases rapidly to a negligible quantity as the ratio of side lengths increases. The writer introduces Equation (16) principally because it is in a form which is easily integrated for determining the torsional distribution factors for the important case of the haunched beam. The use of the exact solution is impractical since it is in the form of a series and, although Equation (2) can be integrated, it yields a very complicated expression.

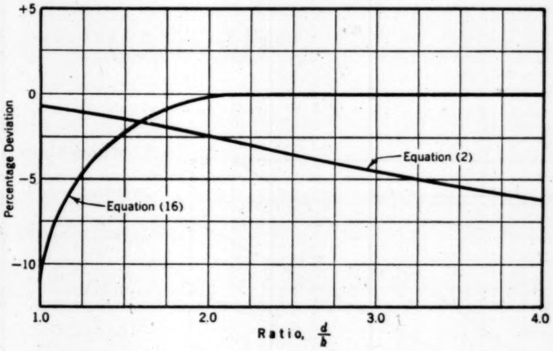

FIG. 7.—DEVIATION OF APPROXIMATE FORMULAS FOR TORSION FACTOR OF RECTANGULAR SECTION FROM EXACT SOLUTION

If a torsional moment is applied at any point of a straight beam, the author in Equations (3*a*) and (3*b*), has shown that the distribution to each end will be inversely proportional to the length of the segment. Such will not be the case for a beam haunched at one end, or at both ends, and this case will now be studied for the straight haunch. The additional notation required is given in Fig. 8, in which d_1 = least depth of haunch; d_2 = depth at wall; and, l_H = length of haunch. The angle of twist caused by a constant torsional moment, M, in an elemental length of haunched section is given by,

$$d\phi = \frac{M}{T\,E_s}\,dx \dots\dots\dots\dots\dots\dots (17)$$

---

[12] "Torsion des Prismes," by Saint-Venant, Paris, 1855.

For the total length of the haunched element, therefore, the total angular twist equals,

$$\phi = \frac{M}{E_s} \int_0^{l_H} \frac{dx}{T} \ldots\ldots\ldots\ldots\ldots\ldots (18)$$

Assume that the breadth, b, is constant and that the torsion factor, T, at any point in the haunch is given by Equation (16). The depth, d, of the haunch at any point will be:

$$d = d_1 + \left(\frac{d_2 - d_1}{l_H} \right) x \ldots\ldots\ldots\ldots\ldots\ldots (19)$$

in which x is the distance from the shallow end of the haunch. Making this substitution in Equations (16) and (18) the integration gives, for the average twist per unit length:

$$\frac{\phi}{L_H} = \frac{3\,M}{b^3\,E_s\,(d_2 - d_1)} \log \left(\frac{d_2 - 0.63\,b}{d_1 - 0.63\,b} \right) \ldots\ldots\ldots\ldots (20)$$

Designating by T_H the effective or average torsion constant over the length of the haunch,

$$T_H = \frac{M\,L_H}{\phi\,E_s} = \frac{b^3\,(d_2 - d_1)}{3 \log \left(\frac{d_2 - 0.63\,b}{d_1 - 0.63\,b} \right)} \ldots\ldots\ldots\ldots (21)$$

or,

$$T_H = C_H\,d_1{}^4 \ldots\ldots\ldots\ldots\ldots\ldots (22)$$

in which C_H is a factor depending on two ratios, $\frac{d_1}{b}$ and $\frac{d_2}{d_1}$, with the restriction that $\frac{d_1}{b} > 1.2 \frac{d_2}{d_1} > 1.0$. Fig. 8 gives values of C_H for different ratios of $\frac{d_1}{b}$ and $\frac{d_2}{d_1}$.

The total angular twist between any point on the uniform section of a haunched beam and the end will be:

$$\phi = \frac{M}{E_s} \left(\frac{L_H}{T_H} + \frac{L_u}{T_u} \right) \ldots (23)$$

in which L_u and T_u are the length and torsion factors for the uniform segment.

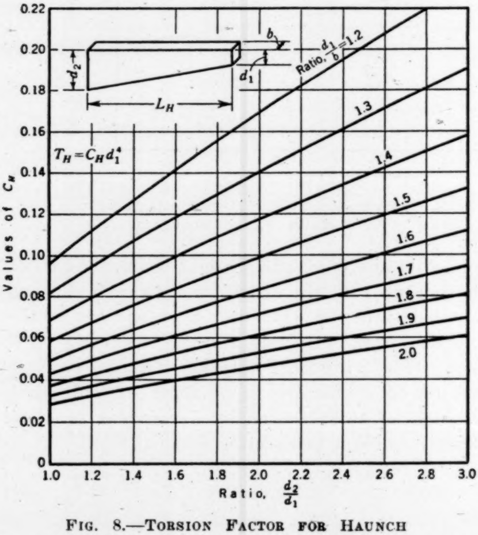

FIG. 8.—TORSION FACTOR FOR HAUNCH

The torsional stiffness for the combined segment will be,

$$K = \frac{1}{\dfrac{L_H}{T_H} + \dfrac{L_u}{T_u}} \quad \text{.......................(24)}$$

and the torsional moment will be distributed to either end in proportion to the torsional stiffness of that particular segment.

The application to an actual case will now be illustrated. Assume a concrete beam 12 in. wide and 20 ft long unsymmetrically haunched as shown in Fig. 9,

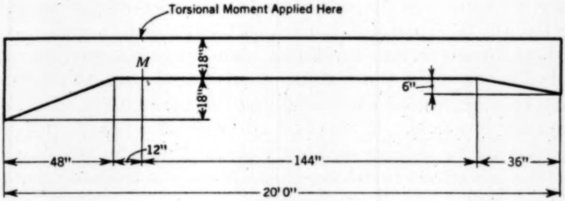

FIG. 9

with a torsional moment, M, applied 5 ft from the left end. For the haunch at the left end: $\frac{d_1}{b} = \frac{18}{12} = 1.5$; $\frac{d_2}{d_1} = \frac{36}{18} = 2.0$; and (see Equation (22)), $T_H = (0.985)\,(18)^4 = 10\,330$ in.^{4} Similarly, for the right haunch, $T_H = 7\,660$ in.^{4} For the uniform section, by Equation (16), $T_u = \frac{18 \times 12^3}{3}\left(1 - \frac{0.63 \times 12}{18}\right) = 6\,010$ in.^{4} Substituting in Equation (24), the torsional stiffnesses of the two parts of the beam are obtained: At the left, $K_L = \frac{1}{\dfrac{48}{10\,330} + \dfrac{12}{6\,010}} = 150.8$; and at the right, $K_R = \frac{1}{\dfrac{144}{6\,010} + \dfrac{36}{7\,660}} = 34.8$. From these values are obtained the distribution factors to give the fixed-end torsional moments, M_f, at the left and at the right ends: At the left end, $M_f = \frac{150.8}{150.8 + 34.8}\,M = 0.812\,M$; and at the right end, $M_f = \frac{34.8}{150.8 + 34.8}\,M = 0.188\,M$, instead of 0.75 and 0.25 for a beam of uniform cross-section.

The torsional stiffness of the entire beam may be obtained by similar computations or directly from K_L and K_R as follows:

$$K = \frac{K_L\,K_R}{K_L + K_R} = \frac{150.8 \times 34.8}{150.8 + 34.8} = 28.3$$

The torsional carry-over factor will always be 1 regardless of haunches, but the bending-moment carry-over and distribution factors will need to be computed by use of the column analogy, from the generalized slope deflection equations, or by reference to previously published diagrams. The analysis then proceeds in a manner analogous to that of the author.

In analyzing similar structures in which the members are steel I-beams instead of concrete, another factor affects the torsional distribution constants appreciably. The usual torsion factor is calculated on the assumptions that end sections are free to warp.[13] If the end sections are restrained from warping, there is a localized increase in torsional stiffness. This increase is insignificant in the case of a rectangular section, but in the case of the I-beam the prevention of the warping of the section at a fixed end has a considerable effect. P. W. Werner, Assoc. M. Am. Soc. C. E., has discussed[14] the general problem of a steel beam fixed at each end and subjected to a twisting moment at any point, which gives, directly, the torsional distribution factors for such a case.

Since these formulas are developed elsewhere, and require considerable routine calculations, only the results of an actual case will be given here. Assume an 8 by 8-in. wide-flanged beam at 67 lb per ft, 16 ft long, fixed at each end, with torsional moment, M, applied at the quarter-point. It is found that the distribution to the shorter segment is 0.818 M and to the longer segment, 0.182 M. The net effect, therefore, is similar to the haunching of a concrete beam, although for an entirely different reason.

The writer has discussed two cases in which the torsional distribution factors cannot be treated as simply as in the case of the rectangular beam of uniform cross-section which was used in the author's example. In some cases, the resulting variations will be negligible, but in other instances they will appreciably affect the analysis.

DEAN PEABODY, JR.,[15] M. AM. SOC. C. E. (by letter).—This paper marks a distinct advance into one of the unexplored areas of reinforced concrete design. The discussion of torsional stiffness and the distribution of the torsional moment in a space frame is of value to the designer.

For the stress analysis at a given section the author makes torsional computations independent of bending computations for fiber stress, shear stress, or diagonal tension. His design equation for the square section is based on the same line of reasoning used for diagonal tension computations and thus makes for consistent design. Equation (13) gives the useful result, $\frac{A_s}{p}$, which enables one to choose the spiral reinforcement immediately.

For a square section the maximum shear stresses occur at the center of each face. The illustrative computations for the problem of Fig. 3 apply to Particle A of a square section (Fig. 10), and the torsion reinforcement should be supplied at Point A for this section. At Particle C on the opposite side the shear stress, v_B, due to the vertical shear force, V, and the torsional shear stress, v_T, due to the torsion couple, M_T, are opposite in direction. For the beam of Fig. 3 the net shear stress at Point C equals 3 lb per sq in. (upward). Therefore, at Point C, no diagonal tension or torsion steel is needed but it is impractical, of course, for the steel to be omitted at C and supplied at A. Particle D has the same stress, v_T, as at A and Fig. 3 shows that an equal or greater percentage of spiral steel is supplied. Due to the slope of the spirals less torsion reinforcement may be supplied at Particle B than at Particle A but, since there is no shear stress, v_B, the full allowable shear stress of 90 lb per sq in. is permissible, although the spiral steel at A was computed for an allowable stress of 46 lb per sq in. The reduced number of spirals at B will be safe, except at sections where the shear force, V, is small. Maximum torsion usually occurs near the support where the shear forces are large. It would appear, then, that the torsional design for square sections is usually adequate when only the particle with maximum total shear stress is considered.

[13] "Structural Beams in Torsion," by Inge Lyse, M. Am. Soc. C. E., and Bruce G. Johnston, Jun. Am. Soc. C. E. *Transactions*, Am. Soc. C. E., Vol. 101 (1936), p. 857.

[14] *Loc. cit.*, p. 912.

[15] Assoc. Prof. of Structural Design, Mass. Inst. Tech., Cambridge, Mass.

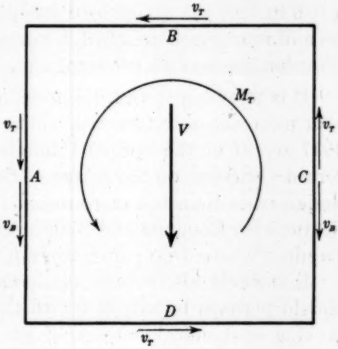

FIG. 10

No recommendation has been made for the allowable shear stresses, but the writer assumes that the customary values for diagonal tension will be used for the total allowable shear stress at Particle A.

The author apparently uses hoops or ties for the spiral steel. It is difficult to wire inclined hoops securely, and the writer believes the added cost of welding these hoops to the longitudinal steel is justified.

Square cross-sections will undoubtedly be chosen for members with large torsional moments, as the author states, but many wall beams and spandrel girders of rectangular shape are subjected to torsional moments. Still more are poured integrally with the slab and the design section is angle or tee-shaped. An authoritative discussion of the design of such sections must wait a comprehensive program of tests and inspection of existing structures.

WALTER H. WHEELER,[16] M. AM. SOC. C. E. (by letter).—The principles set forth in Professor Andersen's paper have important significance when applied to the determination of correct moments of resistance in flat slab structures. Numerous tests on flat slab floors have shown a consistently wide disagreement between the stresses determined by the commonly accepted beam-strip theory of analysis and the actual stresses in the structure under load. Various authorities have explained the discrepancy on the theory that the tensile strength of the concrete was responsible, whereas it would appear from the paper that a more logical explanation would be the torsional resistance of the slab.

Since the torsional resistance is based upon shearing strength and not upon tensile strength of the concrete it would seem logical and proper to give credit to this factor in the flat slab formulas. It does not seem logical to base the analysis of the stresses in a continuous plate supported on columns upon the theory of independent beams supported on columns without any connection between those beams, as is done in the generally accepted flat slab theory.

---

[16] Designing and Cons. Engr., Minneapolis, Minn.

The writer wishes to call attention to the results[17] obtained in the test of the Western Newspaper Union Building, in Chicago, Ill., in 1916, in which four adjacent panels were loaded. The panels were 17 ft 5.5 in. by 19 ft 4.5 in., with a nominal slab thickness of 8.5 in. The actual slab thickness at the edge of the column capitals was 8.35 in. The diameter of the column capitals was 4 ft 6 in. and the design load was 250 lb per sq ft. The test load over the full area of four panels was 913 lb per sq ft and the minimum recovery of the slab after loading was 75 per cent.

It is to be hoped that the torsion theory will be developed for flat slabs and that more accurate formulas will result. It has seemed to the writer that the 1917 report of the Special Committee of the Society on Concrete and Reinforced Concrete, on the design of flat slabs,[18] came much closer to an accurate design basis than the more recent formulas of the Joint Committee on Specifications for Concrete and Reinforced Concrete particularly as to slab thickness required where drop panels are not used.[19]

If the only aim is to be conservative without regard to accuracy, designers should perhaps be satisfied with the present thickness formulas. If they are seeking economical designs which are reasonably accurate, these thickness formulas should be modified.

The progress report of the Joint Committee on Specifications for Concrete and Reinforced Concrete for 1937,[19] gives a basis of determining slab thickness which is reasonably accurate and then recommends that having found this reasonably accurate thickness, 20% be added to it. The Committee proposes adding 20% to the thickness that would be determined as proper according to the 1917 report on the design of flat slabs.[18] Following the Joint Committee's recommendation, the slabs in the Western Newspaper Union Building would be increased from 8.5 in. to approximately 10 in. thick for 3 000-lb concrete.

By the application of the torsion theory to this slab, a reasonable and ready explanation is found for its remarkable performance, and the necessity for increasing the thickness is not apparent.

Further data on thickness of flat slabs with capitals and without drop panels are given in a published report[19] by the writer.

A. Floris,[20] Esq. (by letter).—From the academic point of view, the author's treatment of rigid frames, as systems in space, is valuable and instructive. In practice, however, there may be some question. The solution of the problem, even as applied to the simplest frame, is too complicated to be practicable. Consequently, the application of the method to frames as ordinarily designed will be out of the question, especially if the problem is complicated by side-sway.

[19] Not yet published; see, also, "Comparison of Actual Flat Slab Designs with Code Requirements," *Engineering News-Record*, January 28, 1937, p. 132.

[20] Dipl.-Ing., Los Angeles, Calif.

If one considers that even a beam stressed by pure bending may be subjected to twisting moments by a beam connected to the same column, under a certain angle, it is evident that the proposed method is too theoretical to be practicable. For this reason, designers will continue to consider the analysis of building frames as a plane problem. In general, structural engineers should avoid direct torsion and, if this is not possible, they should at least minimize its effect by modifying the design.

The intent of this discussion is not to criticize the author's efforts, but to emphasize the need for keeping in mind the practical applicability of the theory. Professor Andersen deserves much credit in focusing the attention of engineers on the comparatively unexplored field of torsional resistance of rigid frames.

E. NEIL W. LANE,[21] JUN. AM. SOC. C. E. (by letter).—Due mainly to the desire for simplicity and a lack of adequate information, torsional stresses have been largely ignored in structural design. Generally, they are small in comparison with the flexural and shearing stresses, which makes a two-dimensional solution satisfactory for most structural problems.

Professor Andersen shows the application of the moment distribution method to the analysis of three-dimensional frames, but dismisses the solution by the slope deflection method with a general statement of procedure. Since certain methods are more adaptable to one type of problem than others, it is deemed advisable to show the application of the slope deflection method to a frame similar to that analyzed in Table 1.

The writer has assumed a length of 15 ft for the side members, and a modulus of elasticity of 3 000 000 lb per sq in. The position of the assumed 10-in. width of the members, relative to the assumed 24-in. depth, was such that the members, *A B*, *A C*, *A′ B′*, and *A′ C′*, were to take the greater proportion of the external torsion; and the frame, *DA A′D′*, was to take the greater proportion of the flexure.

Using stiffnesses, as in Equations (4) and (6), the following joint equations are obtained:

$$M_{f(AA')} + M_{f(A'D)} + M_{t(AB)} + M_{t(AC)} = 25.0\,\theta_A + 2.4\,\theta_{A'} - 1.0 = 0 \quad \text{(25a)}$$

$$M_{f(A'A)} + M_{f(A'D')} + M_{t(A'B')} + M_{t(A'C')} = 50.0\,\theta_{A'} + 4.8\,\theta_A + 1.0 = 0 \quad \text{(25b)}$$

$$M_{f(AB)} + M_{f(AC)} + M_{f(AD)} + M_{t(AM)} = 145.9\,\phi_A - 1.0 = 0 \quad \text{(25c)}$$

$$M_{f(A'B')} + M_{f(A'C')} + M_{f(A'D')} + M_{t(A'M)} = 265.4\,\phi_{A'} - 1.0 = 0 \quad \text{(25d)}$$

In solving, the rotations become $\theta_A = +0.0423$ radian, and $\theta_{A'} = -0.0242$ radian in the plane, *DA A′D′*; and $\phi_A = -0.00685$ radian, and $\phi_{A'} = -0.00367$ radian in the planes, *AB CD*, and *A′B′ C′D′*, respectively. Thus, a torsional moment of $+ 1.96 \times 10^6$ in.-lb and a flexural moment of $— 6.85 \times 10^6$ in.-lb are obtained at End *A* of the member, *A M A′*. Side-sway, although present, has been neglected to make this solution more comparable to the moment distribution method, as shown by the author.

---

[21] Bridge Detailer, State Dept. of Roads and Irrig., Lincoln, Nebr.

It is hoped that Professor Andersen's worthy paper will interest others in the study of torsional analysis in connection with three-dimensional structural frameworks.

A. A. Eremin,[22] Assoc. M. Am. Soc. C. E. (by letter).—An interesting method of distributing torsion moments in rigid frames is developed in this paper. Professor Andersen assumed that the centers of joints in rigid frames remain at their original position at all variation of loading sustained by the frame. This assumption is generally used in computing torsion moments by the method of least work. It simplifies computation without serious error for practical purposes.

In the distribution of the bending moments in rigid frames a convenient rule for checking the computations was derived: The sum of bending moments at any joint in a rigid frame, at any loading, is equal to zero. There is no similar simple rule for checking computations of the torsion moments in rigid frames. However, a simplified approximate computation of torsion moments may be used for checking of the more exact computations.

The relation of the torsion moments at the ends of Member $A\ A'$ in the rigid frame shown in Table 1 may be expressed by the following equations:

$$M_A + M_A' = M \ldots\ldots\ldots\ldots\ldots\ldots\ldots (26)$$

and,

$$K_{TA}\, M_A\, (1 - \Sigma\, K_A)\, m + K_{TA}'\, M_A'\, (1 - \Sigma\, K_A')\, n = 0 \ldots\ldots (27)$$

in which, M_A and M_A' are the torsion moments in the member, $A\ A'$, at the ends, A and A', respectively; K_{TA}, K_{TA}' are torsion stiffnesses in the member, $A\ A'$, at the ends, A and A', respectively; and $\Sigma\, K_A$, $\Sigma\, K_A'$ are the sum of the stiffness factors of the adjacent members at Ends A and A', respectively.

Solving Equations (26) and (27) simultaneously, the torsion moments, M_A and M_A', may be determined. The torsion moments in Member $A\ A'$, with the loading considered in Table 1 as computed by Equations (26) and (27), are $M_A = 200$ and $M_A' = 100$. These moments are the same as those computed for the fixed ends in Member $A\ A'$. Evidently, a slight degree of fixation at the ends of Member $A\ A'$, caused by the action of adjacent members on the distributed torsion moments, is due to their low flexural resistance and the symmetry of the frame. Evidently, the maximum error of computed torsion moments is only 8 per cent. This error is not excessive considering various approximate assumptions used in the more exact method. The distribution of torsion moments in a multiple-story, rigid frame may likewise be computed by Equations (26) and (27) by considering the frame to be composed of elementary frames similar to that shown in Table 1. Therefore Equations (26) and (27) may be used for approximate computations of torsion moments and for checking the distribution of torsion moments determined by the more exact method.

---

[22] Associate Bridge Designing Engr., Div. of Highways, State Dept. of Public Works, Sacramento, Calif.

Harold E. Wessman,[23] M. Am. Soc. C. E. (by letter).—Two main elements of value are contained in this paper: First, it develops a logical procedure for the design of a reinforced concrete member, subject to a known torsional moment; and second, it focuses attention, indirectly, on a typical, but naive, procedure of designing a slab, beam, and girder floor. The writer wishes that more space had been devoted to the second element in order to emphasize the uncertainties existing in this problem of torsion as related to reinforced concrete structures. There is no doubt that the usual procedure of slicing a slab into a strip and designing the slab, the beam, and the girder as isolated units subject to forces and moments in one plane only has the virtue of convenience; but is it accurate enough for all cases? The paper may stimulate some new thinking about the question of accounting for torsion and treating a structure as a space frame.

It is not difficult to extend the theory of moment distribution in a plane to moment and torsion distribution in three dimensions, in order to get bending moments and twisting moments in the various units which make up a space frame. It is very difficult, however, to interpret the results in a monolithic, reinforced concrete floor system.

Several years ago the writer directed a graduate thesis[24] on the subject, "The Effect of Torsional Resistance of Girders on the Bending Moments in Connecting Beams." Varying ratios of torsion stiffness factors to bending stiffness factors were assumed and maximum moments then determined. For certain ratios of torsional stiffness to bending stiffness, beam spans were practically fixed at the ends. Moment coefficients in cases like these, even if the spans are equal and the live-dead ratio less than three, may be considerably in error if specified by code rules.

It is not difficult to establish torsion constants for isolated rectangular sections or for sections composed of an assembly of rectangles if they are assumed to be homogeneous, isotropic, and perfectly elastic; but, what are the boundary dimensions of a beam with a floor slab upon it? Where is the center of rotation of a girder which is part of a monolithic slab, beam, and girder floor? Will the slab tend to prevent any rotation of the beams and girders, thus making the torsion constant equal to infinity, and making all spans fixed at their terminals? How about the rotations of the ends of beams due to the deflection of the girder to which they connect, due to bending? These questions indicate the complexity of the problem. It may be that typical design procedure, even if it is admittedly naive, is the best that can be devised. This much can be said for usual design procedure: Definite paths of resistance are made strong enough to support the loads on the structure, even if the paths of resistance in the actual structure may not be exactly those which are prescribed in the analysis.

Paul Andersen,[25] Assoc. M. Am. Soc. C. E. (by letter).—The purpose of this paper was twofold: First, to present the procedure of determining torsional moments in reinforced concrete structures; and, second, to present a rational design method for reinforcing against torsion. The latter received scant attention in the discussion.

[23] Prof. of Structural Eng., Coll. of Eng., New York Univ., New York, N. Y.

[24] Thesis submitted to the University of Iowa in 1935 by William Gallagher, in partial fulfillment of the requirements for the degree of Master of Science in Civil Engineering.

[25] Asst. Prof. of Structural Eng., Univ. of Minnesota, Minneapolis, Minn.

The practical applicability of the theory is questioned by Mr. Floris. The writer fully agrees that, in general, structural engineers should avoid direct torsion and, if that is not possible, they should at least minimize its effect by modifying the design. The crane girder, the balcony girder, and the beam curved in plan are examples of types of structural members in which torsion cannot be eliminated. Professor Wessman emphasizes the difficulty of finding torsional moments where these are modified by the presence of monolithic floor-slabs and connecting beams. If the torsion is due solely to deflection and the bending of connecting members, it is probably safe to ignore it and (as expressed by Professor Wessman) provide "definite paths of resistance strong enough to support the loads on the structure, even if the paths of resistance in the actual structure may not be exactly those which are prescribed in the analysis."

The writer favors the suggested simplification of Table 2 as presented by Mr. Deans. In the writer's opinion, the sign convention recommended by Professor Grinter is the one best suited for the study of continuity in space frames. Professor Grinter also calls attention to the fact that torsional fixed-end moments and carry-over factors for haunched beams must be found by integration. In this connection, the writer is pleased to acknowledge Mr. Johnston's valuable contribution to the discussion. Fig. 8 will enable the designer to compute torsion factors for haunched beams.

Mr. Lane shows how the illustrative example in Fig. 3 can be solved by the slope deflection method. This approach, together with Mr. Eremin's approximate method, offers the designer various methods of computing torsional moments. Professor Peabody indicates the main differences between torsional shear and what is generally known as vertical shear.

The writer does not agree with Mr. Wheeler's statement that torsional resistance is based upon shearing strength and not upon the tensile strength of the concrete. Torsion failures of concrete are diagonal tension failures and torsion reinforcement is tension reinforcement.

ECONOMICS OF THE OHIO RIVER IMPROVEMENT

By C. L. Hall,[1] M. Am. Soc. C. E.

With Discussion by Messrs. Eugene L. Grant, Fred Lavis, O. Slack Barrett, Edmund L. Daley and Forrest E. Byrns, J. E. Willoughby and W. D. Faucette, W. E. R. Covell, and C. L. Hall

Synopsis

Brief descriptions of the improved Ohio River are given in this paper, including methods used in navigating it, and the character of the freight borne upon it. The problem presented is then stated, namely, is the public compensated for the heavy national expenditures on the improvement? Commercial navigation costs are determined as accurately as possible, on a ton-mile basis, for each class of freight. Government costs are analyzed on a ton-mile basis, applicable to all classes of freight. The sum of these two costs is compared with rail rates for various commodities, both analytically and graphically. The conclusion is reached that the public has been compensated for its expenditures on the Ohio River improvement, and that this fact tends to become more and more evident every year.

Physical Situation

The Ohio River is formed by the confluence of the Allegheny and Monongahela Rivers, at Pittsburgh, Pa., and discharges into the Mississippi River at Cairo, Ill. The distance from Pittsburgh to the mouth, measured by water, is 981 miles. (The mile used in this paper is the statute mile of 5 280 ft, or 1 609.4 m. The ton is the short ton of 2 000 lb, or 907.18 kg.) The river is improved by four fixed dams, and forty-two movable (or navigable) dams. Two of the fixed dams, recently constructed, have movable crests.[2] At fixed dams, traffic always moves through the locks; at movable dams, it moves through the locks at low water. At medium and high stages, the movable dams are lowered, and traffic moves in the open river. The percentage of time during which

---

Note.—Published in October, 1937, *Proceedings*.

[1] Col., Corps of Engrs., U. S. Army, Commanding 1st Engrs., U. S. Army, Fort DuPont, Delaware.

[2] Descriptions of the project are contained in the Annual Repts., Chf. of Engrs., U. S. Army, in Rept. for 1935, pp. 1043–1047.

open-river traffic is possible, varies from 28 at the up-stream movable dam, to 50 at the down-stream dam. At the Falls of the Ohio, at Louisville, Ky., there is a very high movable dam; and traffic moves through the locks there for 95% of the time. Fixed dams and the dam at Louisville are provided with twin locks, whereas the other movable dams have a single lock. The standard lock dimensions are 600 ft by 110 ft. The operation of the system has been described by the writer elsewhere.[3] The minimum depth of the channel is 9 ft, allowing a loaded draft of a little more than 8 ft. However, except at times of extreme low water, barges can be loaded to 9 ft.

Traffic is subject to interruption by high water, ice, and fog. Interruptions by high water at fixed dams are due to the passage of the water over the lock-gates, preventing their functioning. Technically, there are no interruptions by high water at movable dams, but, at very high stages, navigation becomes dangerous. Moreover, the economic functioning of terminals becomes impossible when the river is out of its banks. Ice in sufficient quantities makes navigation impossible. Ice at low water may also compel the lowering of movable dams, making the useful depth too small for economical navigation.[4] At certain seasons of the year, fog at night and in the early morning causes a suspension of traffic.

Conditions from year to year differ to such an extent that it cannot be said that there is any normal number of days during which traffic is interrupted. The median number of days, at Cincinnati, Ohio, about half-way down the river, for the years 1919 to 1935, inclusive, was as follows: By high water, less than one day; by ice, three days; and by low water following ice, less than one day. (These data were obtained from study of official records of the U. S. Engineer Office, at Cincinnati.) Traffic is tied up on account of fog about 80 hr per yr, but never for more than 12 hr at a time. (Little has been published on fog. The information used has been secured by the writer in private discussion with operators.)

The economics of Ohio River transportation are materially influenced by the improvement of five principal tributaries: The Allegheny and Monongahela Rivers, which form the Ohio, at Pittsburgh; the Kanawha River, which joins the Ohio, at Point Pleasant, W. Va. (Mile 265.7); the Cumberland River, at Smithland, Ky. (Mile 920.4); and the Tennessee River at Paducah, Ky. (Mile 934.5). All these tributaries have been at least partly improved by the construction of locks and dams, thereby permitting year-round navigation from and to the Ohio River. Of lesser importance are the other improved tributaries: Muskingum, Little Kanawha, Big Sandy, Kentucky, and Green Rivers.

History of the Improvement

The first appropriation for the improvement of the Ohio River was made by Congress in 1824. Allotments to the year 1874 were for an open-channel improvement, consisting of the construction of dikes, removal of snags and wrecks, and some dredging. This work permitted navigation at medium and high stages. During this period, the Government also purchased an interest in the Louisville and Portland Canal, which passes traffic around the Falls at Louisville. In 1874, a plan was proposed for canalizing the Ohio River by means of a system of movable dams, in order to secure a depth of 6 ft. The first dam constructed under this plan was completed in 1884, at Davis Island, about 5 miles down stream from Pittsburgh. Work under the plan of 1874 progressed slowly. From time to time, the plan was modified. In 1910, a project was adopted by Congress, which provided for the canalization of the river by a system of movable dams, which established a channel depth of 9 ft, substantially as subsequently executed. This project was completed[5] in 1929. Except for some early work on the Louisville and Portland Canal, the entire improvement has been in charge of the Corps of Engineers, United States Army.

NATURE OF TRAFFIC

Fig 1. shows, graphically, the traffic on the Ohio River for the calendar year 1934.[6] Although the tonnage differs from year to year, the general picture presented by Fig. 1 remains fairly constant, the principal alterations in recent years being the considerable increase in movement of petroleum products, and a decrease in the short-haul sand and gravel movements. The character of Ohio River commerce can probably be best explained by a discussion and amplification of the information contained in Fig. 1.

Steel is the most valuable cargo carried on the river, and the second most important in ton-mileage (26%). Manufactured steel is habitually loaded in barges at points in the Pittsburgh District. A small portion of it is discharged at Ohio River ports, but most of it is consigned to Lower Mississippi River towns. Practically all this steel is moved by contract carriers, or by private carriers owned by the steel companies, and is down-stream movement. There is a return cargo in the form of scrap steel, gasoline, sulfur, and fluorspar, which is collected at Lower Mississippi and Lower Ohio ports, for consignment to Upper Ohio River ports.

Coal forms the largest item, both in tonnage and in ton-mileage (42%), in Ohio River traffic. About 4 600 000[7] tons of coal pass out of the Monongahela every year. This coal is practically all unloaded and consumed at manufacturing plants in the Pittsburgh District. Almost none of it moves as far down stream as Wheeling (Mile 90.5). There is a movement from tipples in the pools of Locks Nos. 13 and 14 (Miles 96.1 to 114.0) in both directions, but principally up stream, to near-by manufacturing plants. In the stretch of river from below Wheeling to the mouth of the Kanawha River (Mile 265.7), practically no coal moves. A considerable tonnage of coal moves out of that river by water to Middle Ohio River plants. A much larger quantity moves from Huntington, W. Va., tipples (Mile 308.3). Some of this is discharged at plants in the Ironton-Portsmouth District (Miles 327.2 to 356.0). Much the greater proportion is unloaded at Cincinnati (Mile 470.2), and just below. A small quantity reaches Louisville (Mile 603.7). From Louisville to Caseyville, Ky. (Mile 871.2), a small quantity of coal moves on the river, principally from the Green River (Mile 784.2). From Caseyville to the mouth, there is a relatively small movement of coal consigned to Lower Ohio and Mississippi River towns. Practically all the coal moved on the river is transported by private carriers; those in the Pittsburgh District are generally owned by steel companies, and those in other parts of the river by coal companies. Except for the small tonnage which moves up stream from the pools of Locks Nos. 13 and 14, and on the Lower Ohio River, all coal moves down stream. There are no appreciable return cargoes on coal barges.

[5] Annual Rept. of the Chf. of Engrs., U. S. Army, 1935, pp. 1043–1044; House Doc. No. 306, 74th Cong., 1st Session, pp. 134–137.

[6] From an official chart prepared from information submitted by carriers in accordance with law.

[7] Obtained by averaging the 1930–1934 tonnages of the Monongahela River, Annual Repts., Chf. of Engrs., U. S. Army, fiscal years, 1931–35, Pt. 2.

Petroleum products (11% in ton-mileage) move in both directions in special tank barges, normally from riparian storage tanks to riparian delivery tanks. However, the major movement is in the Lower Ohio River, from storage tanks along the Mississippi River and its other tributaries. These products are usually transported in private barges, but many of the barges are propelled by towboats engaged in contract or common carriage. About 75% of the movement (in ton-mileage) is up stream.

Sand and gravel (6% in ton-mileage) is dredged from sand and gravel bars in the river and moves in both directions in privately owned barges for comparatively short distances to delivery points.

Miscellaneous freight (13% in ton-mileage) moves in packet-boats, and also in barges owned by common and contract carriers, although some fluorspar from Lower Ohio River ports is carried up stream by private carriers owned by steel companies. Miscellaneous freight moves in both directions.

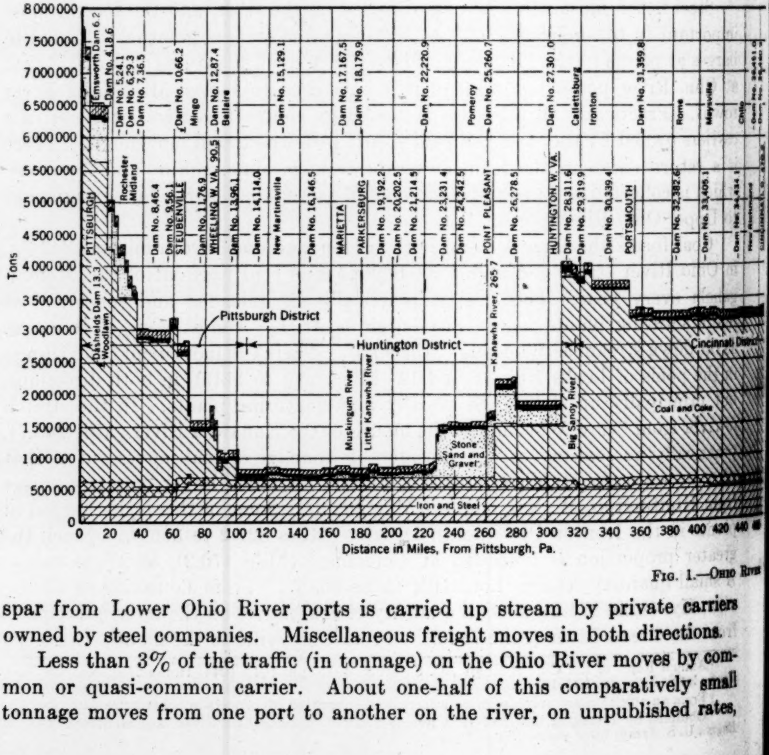

Fig. 1.—Ohio Riv

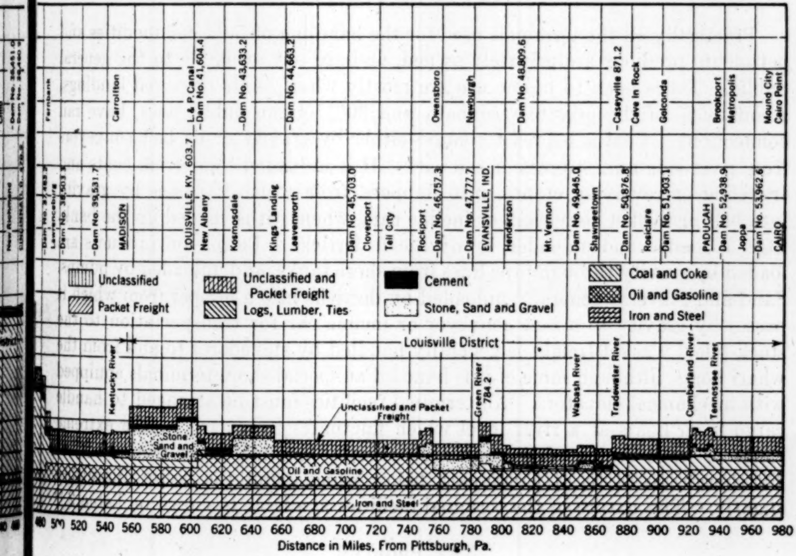
Less than 3% of the traffic (in tonnage) on the Ohio River moves by common or quasi-common carrier. About one-half of this comparatively small tonnage moves from one port to another on the river, on unpublished rates, or on rates frequently changed on short notice, and the remainder, the river-rail common-carrier traffic, moves on rates "established" in the railroad sense of the word.

Character of Boats

Bulk freight is habitually carried in steel barges normally about 26 ft by 175 ft, or in wooden barges about 26 ft by 135 ft. These carriers are propelled in fleets of from six to eighteen barges by stern-wheel or screw towboats, which invariably push rather than tow the barges. In the transportation of coal in wooden barges, tows of twenty-four barges are not infrequent. The towboats vary from 30 hp to 2 200 hp, with an average draft of from 4 to 6 ft. Package and perishable freight may be carried either in tows of closed barges (a method which is increasing in popularity among river operators), or on packet-boats, similar in type to the packets of the Nineteenth Century. Petroleum and other liquid products are carried in specially constructed tank barges. A few of the towboats are of the tunnel screw type. This type of towboat is becoming increasingly popular on Western rivers as is the Diesel engine instead of the steam engine. Many of the newer vessels on the Ohio River are of the Diesel, screw type.[8]



Rive onnage Graph, 1934

The size of the locks at Ohio River dams has been a controlling factor in the construction of barges. A tow of barges, 26 ft wide, four abreast (which is standard on the Ohio River), occupies a minimum of 104 ft in a lock 110 ft wide. In the purchase of new barge equipment, there is a trend toward the construction of barges 35 ft wide for assembly in tows of three abreast. The nature of the floating equipment using the river is shown in Table 1.[9]

---

[8] The technique of inland navigation is described in the reports of the Towboat Board: H. R. Doc. No. 857, 63d Cong., 2d Session; H. R. Doc. No. 108, 67th Cong., 1st Sess.; and mimeographed report of June 17, 1929. Information on the character of vessels now using the Ohio River has been obtained from the U. S. Engineer Office, at Cincinnati, Ohio.

CHARACTER OF TERMINALS

Practically all the terminals used for the handling of bulk commodities and petroleum products are privately owned, and are not available to the general public. Those open to public use are mostly wharf boats or paved landings. About 65% of the private terminals, and 30% of the public ones, have rail connections. Coal is loaded to barges either by gravity or by belt conveyors from river-side mine tipples or rail cars. It is unloaded by derrick-boats and traveling or revolving cranes, into hoppers, from which it passes by gravity into belt or bucket conveyors or incline cars, whence it is carried up the bank. Steel is loaded and unloaded by overhead derricks. Petroleum products are loaded by gravity through pipe lines from shore tanks, and unloaded by pumps. Sand and gravel is generally unloaded by derricks into a hopper from which it passes by gravity to a belt conveyor or incline car for transportation to the stock-pile. Packet freight is generally handled by stevedores to and from the wharf boats, although some of it is handled at special shore terminals equipped with mechanical elevators. All terminal facilities must be arranged to handle cargo from boats at a river level which fluctuates irregularly. The extreme range of stage during which traffic is normally handled varies from 16 ft, at Pittsburgh, to 44 ft, at Cincinnati, below which point the figure diminishes slightly. The nature of the terminal facilities available is shown in Table 2.[10]

THE PROBLEM

Freight moves on the Ohio River because it can be transported more cheaply by water carriers than by land carriers. It can be transported at low rates because engineering works have been built on the river at the expense of the taxpayer. Since no tolls are charged, the Treasury derives no direct return. The public obtains an indirect return in the reduced net cost of water-transported articles consumed. The problem is to compare the engineering costs of the improvement with the value of the public benefits. This Ohio River question, of course, is a part of a larger national inland waterways problem,[11] which is now arousing great interest among American engineers and economists. (For example, John S. Worley, M. Am. Soc. C. E., in 1936,[12] stated that "the operation on this [Ohio] river gives little encouragement that any justification will be found.") It is also receiving international attention, the International Congress of Navigation in 1935 having particularly requested its members to prepare reports on the economic value of improved inland waterways.[13]

PERIODS OF TIME COVERED

This paper, so far as its facts, as distinct from their analysis, are concerned, is a sequel to a report of 1926, by C. W. Kutz, M. Am. Soc. C. E., which was presented later to the public under the title of "The Relations of the Ohio River and Its Tributaries to Transportation in the United States."[14] No attempt has been made to restudy the investigations covering the period from 1905 to 1925 treated by General Kutz. However, improved collection of commercial statistics by the Engineer Department now permits the acquisition of information in regard to ton-mileage, as distinct from tonnage. When no such information was available, the segregation of credit for commerce moving on two or more rivers had to be made separately for each form of haul. Now, credit for commerce not moving on a single river can easily be determined from ton-mileage charts, after an average cost per ton-mile for the commodity has been established.

The commercial statistics are by calendar years, whereas Federal expenditures are reported by fiscal year (July 1 to June 30). This six-months time lag of benefits over costs will obviously be of no importance over a long period, and has been disregarded. Commercial statistics are closed as of December 31, 1934, and expenditures as of June 30, 1934, since it was convenient to establish limiting dates based on publications available at the time the study was initiated. (See heading, "Trends of Commerce" for a discussion of the most recent data.)

ASSUMPTIONS

As is necessary in all generalizations from data taken from sources of diversified origin, certain assumptions have been made in the statistical work of this study:

> Assumption (1).—The entire reduction of costs in transportation of freight, due to the existence of an improved waterway on the Ohio River, is passed on to the public in the form of lower prices of the goods transported, and hence becomes a public saving.

Assumption (1) complies with the principles of Nineteenth Century economics. When goods are manufactured at *A* and sold at *B*, the savings in transportation over the line, *A B*, are reflected in the lower price of goods at *B*. The assertion is undoubtedly true in a perfectly free economy. It may be doubted whether a perfectly free economy ever has existed, but it certainly does not exist now on the Ohio River. The two most important items of commerce—coal and steel—are manufactured, transported, and, to a large extent, distributed by firms which, on a small scale, correspond to what the Germans call "vertical trusts." Thus, the same firm, under different forms of capitalization, will own coal mines, steel plants, and steel yards, which are essentially jobbers' supply stations. They will also own towing companies for the transportation of coal and manufactured steel. Except over the comparatively short distances during which their raw materials move by common carrier, the manufacture, distribution, and sale of water-borne steel is handled under one corporate management. The same applies to coal companies, which own mines, tipples, transportation lines, and storage yards.

---

[14] *Transactions*, Am. Soc. C. E., Vol. 89 (1926), pp. 1106–1122.

Free competition between the point of production and the point of transfer to the retailer does not exist. At the same time, there is great competition between corporate enterprises having more or less widely separated points of production, and almost adjacent points of distribution. This tends to set up free economic competition between the corporate enterprises, under which the economies due to water transportation tend to be passed on to the consumer. However, the extent to which this saving is transferred is not susceptible of accurate determination. Under certain circumstances it may become zero. The following testimony[15] of a coal operator is apposite:

> "The cost of the coal to our customers at the inland destinations is identically the same, regardless of whether the coal is shipped all-rail from the mines or ex-river from Cincinnati or Addyston."

The comparatively large industrial consumers, however, are undoubtedly able to secure reductions in cost of the delivered coal by bargaining. Where these consumers are utilities, and, to some extent, where they are not, this saving is passed on. Indeed, it would be surprising in a competitive market if savings in cost of transportation were not reflected in reduced retail costs. In course of time, as the number of firms technically fitted to engage in water transportation becomes greater, the assumption will become more and more true. It will thus eventually become accurate. As far as Assumption (1) is in error, the error is in favor of the waterway.

Assumption (2).—The reduction of cost in transportation of freight is equal to the rail cost of transporting the freight actually carried by water, minus the water cost of transporting that same freight.

In general, water-borne freight is some form of bulk commodity, habitually transported by rail where no water route is available. It is logical, therefore, to compare rail and water costs. The difficulty is that rail costs cannot be determined, and it is necessary to use rail rates. If one could use water rates, comparison would still be logical. However, except for the very limited common carrier traffic, water rates are as difficult of determination as rail costs. Therefore, it has been necessary to compare rail rates (in the general case), with water costs, adding to the latter a 6% return on the invested capital. The water costs consist of the line-haul cost of freight, plus the rail rate from the origin to one port and from the other port to the destination (if there has been any rail travel), together with a carefully determined terminal differential. Where the terminal differential is in favor of the waterway, as is apparently the case with liquid petroleum products, none has been included. Assumption (2) is reasonably accurate.

Assumption (3).—The reduction in the cost of ferriage over a waterway, caused by its improvement, is not a public saving.

Ferry transportation is obviously cheaper in a canalized river than in an open one. On the other hand, owing to the increased number of bridges, this form of traffic is of diminishing importance. There seems to have been no reduction in tolls as a consequence of canalization, so that no direct benefit has been passed on to the public. If there is any error in Assumption (3) it is against the waterway.

---

[15] Testimony of H. E. Webster for the West Virginia Coal & Coke Corporation, Interstate Commerce Comm. Docket No. 25 933.

> Assumption (4).—The United States Engineer Department costs include the entire Federal cost of the improvement.

Certain expenditures of the Federal Lighthouse Service and of the Steamboat Inspection Service are obviously for the benefit of Ohio River transportation. It has proved impossible in practice to segregate these costs for each waterway, because the books of the Services do not show any such breakdown. The costs are so trifling when compared with those of the Engineer Department that it is not worth while to spend too much time on their study. Assumption (4) is favorable to the waterway.

> Assumption (5).—In comparing expenditures and benefits, no allowance has been made for taxes.

There is considerable claim that annual water costs should be charged with an arbitrary percentage of the existing value of the Federal improvement made in the stream. There would be something to say for this if it were applied generally to all carriers moving on public highways. Nobody, however, charges the cost of lighting an airway against an airline. Moreover, there is a countervailing tax benefit, of which no account is taken, the omission of which might be even more adverse to the waterway than an arbitrary tax allowance is beneficial. The carriers pay taxes on terminal properties which would have practically no value if the waterway were not improved. They pay taxes on floating plant which would not exist if there were no waterway. They pay income taxes. The first two forms of tax are presumably reflected in costs, but the income taxes are not. No determination can be made of them, because it would be necessary to set up a counter claim for the reduced income tax of competing forms of transportation. This would create a problem impossible of solution. It is not altogether unfair to state that the attempt to determine the taxable value of the waterway is about as difficult as that of determining the taxable value of Central Park in New York City. The entire value of the real estate abutting on that Park is based on its existence. A large part of the value of all real estate in the Ohio River basin is similarly based on the existence of the improvements. Under such circumstances, there is no rational method of assessing a charge for unpaid taxes against the waterway. There is no method of determining whether or not Assumption (5) is beneficial to the waterway.

To summarize, Assumptions (1) to (5), taken as a whole, may be regarded as favorable to the waterway, but the extent of this prejudice tends to diminish with time and, for all practical purposes, may eventually disappear.

Carrier Costs of Water-Borne Freight

The most difficult problem statistically in any study of water transportation is the determination of the actual costs incurred by the private or contract carrier, in moving bulk products concerning which he is not required to quote any rates to any one. By an analysis of figures furnished confidentially by various carriers in 1926, General Kutz prepared a graph of the costs of transporting coal by water.[16] Since that date, the movement of coal from the Kanawha River and from Huntington to Cincinnati, has become the greatest single factor in tonnage of any Ohio River movement, except the short haul immediately down stream from Pittsburgh. The private coal carriers in this area decline to furnish cost figures, even confidentially. It is not believed that the Pittsburgh coal carriers have been able to reduce their costs much below those shown in the Kutz study—that is, about 3 mills per ton-mile. The line costs of the Huntington-Cincinnati traffic seem to have been brought to a figure below this point. The best indications available to the writer are that the cost to the most economical carrier is now less than 2 mills per ton-mile. A hypothetical study by a prospective operator, which was shown to the writer, gives a still lower figure.

The steel carriers, although unwilling to be quoted individually, make no particular secret of the fact that the line cost of transporting steel for long hauls on the Ohio River is not more than 3 mills per ton-mile. A large contract carrier has submitted to the writer cost data which indicate that his operating cost for 1934, including a 5% return on the investment, was slightly less than 2 mills per ton-mile. A recent official report[17] cites 3 mills per ton-mile for Ohio River traffic in general, but this includes an arbitrary 20% for terminal costs. In computing the savings of the two all-important items of coal and steel, the writer has, in general, used line-haul costs of 2 and 3 mills per ton-mile for principal coal movements, and about 3 mills per ton-mile for steel. These figures are thus slightly higher than what might be termed the general opinion of the industry. The errors, if any, being in favor of decreased costs, are against the waterway. Although no statistical certainty can be reached, it seems probable that the errors against the waterway caused by assuming too high line-haul costs more than balance the errors in its favor caused by the five assumptions previously stated. The cost of hauling petroleum products is even more difficult to determine. The capital investment in the specialized barges (generally used) is so large a part of the total cost that density of traffic, or factor of use, really settles the matter of profit or loss. The operating costs, of course, are increased by the much greater proportion of up-stream traffic encountered in this trade. The writer has used values for savings in this connection which he regards as conservative, and which were based on quotations received from contract carriers. It is regretted that the confidential character of the basic figures obtained prevents a direct statement of the ton-mile cost upon which the savings given in Tables 3 and 4 were based.

The method of computing sand and gravel savings is sufficiently explained in the Appendix. The terminal costs of handling these products are so large, and the mileage of any particular lot is usually so small, that the line cost of transportation (independent of terminal charges) is not a controlling factor in determining the savings.

* Allegheny River coal included.

On account of the overwhelming importance of the four products, coal, steel, petroleum, and sand and gravel, it has not been deemed necessary to discuss herein the ton-mile cost of transporting the other products upon which the savings have been based. A discussion of each significant item is contained in the Appendix.

NET SAVINGS

In general, the costs on each of the more commonly used routes for each important commodity were determined by multiplying the ton-mileage moved by the average cost per ton-mile as estimated herein (see heading "Carrier Costs of Water-Borne Freight"), adding the terminal differential between rail and water transfers (except in the case of petroleum where it is in favor of the waterway), and also adding the actual rate for rail haul where (as in the general case) the commodity was hauled either to the river before transportation, from the river after transportation, or both. These costs were deducted from the comparative rail rates, and the gross savings established. From this

value, the saving per ton-mile was easily obtained. In a small number of cases where published rates were available, these rates were used in lieu of costs. In general, since it was impracticable to obtain water rates or costs for each year separately, the savings for 1934 were calculated, and the average savings per ton-mile for the years, 1926 to 1934, were apportioned as explained in the Appendix. For the savings prior to 1926 the figures used by General Kutz in an official report were adopted. As explained previously, the break-down by ton-miles was impracticable for earlier years. The Appendix gives details of calculation for each of the more important items.

Official records (Annual Reports of the Chief of Engineers, for each fiscal year, Government Printing Office) give the tonnage and (in recent years) the ton-mileage of each commodity. After the unit saving per ton-mile for each commodity was determined, as shown in Table 3, simple arithmetic gave the commodity savings in dollars. These savings are summarized in Column (39), Table 3, and Column (48), Table 4. The values there given have been used as the net public benefit, with which the annual Federal costs must be compared (Column (15), Table 5).

GOVERNMENT COSTS

The determination of the Government costs is the simplest part of this study. Full data are available in the Annual Reports of the Chief of Engineers. The only explanation required refers to a few necessary assumptions in the statistics. The interest charge on Government money has been assumed as 4 per cent. This is high for recent years, but not excessively so. The interest during construction has been assumed at 2% for the year the money was spent; that is, it is assumed that costs were uniform throughout the year. The depreciation has been charged from the year of completion. In every case in which the lock has not been retired from service in less time, the life of the structure has been assumed as 40 yr. A straight-line depreciation has been assumed over that period. Where a lock has either been retired, or is due to be retired after less than 40 yr in service, the actual life of the lock, in years, has been determined, and a straight-line depreciation taken over that period.

In determining the remaining investment, or the surplus in the cumulated capital account (Columns (23) and (24), Table 5), depreciation of structures (Columns (14), Table 5) has been subtracted. This was done because the annual depreciation of the structures had already been added into the annual charges (Column (15), Table 5), thereby reducing the annual profit by the amount of the depreciation, which, in turn, reduced the net annual capital charges (Column (21), Table 5). Since the depreciation was thus added as a charge for the year, the remaining investment of the Government in the structures was obviously reduced by that amount. With these explanations, Table 5 should become perfectly clear.

Comparison

The graphical analysis in Fig. 2 shows the manner in which at first the annual charges (Column (15), Table 5) increased much more rapidly than the commercial savings (Column (16), Table 5), then how the savings overtook those charges until the onset of the depression, and then how rapidly these savings have advanced since 1932. Fig. 3 shows the manner in which the capital charges (Column (10), Table 5), as shown on the Government books, have, of course, tended to increase while the capital account (Columns (23) and (24), Table 5), from an investor's standpoint, assuming a public profit from savings, has tended recently to decrease. The relation of savings to expenses is shown analytically in Column (19), Table 5, in which the ratio, 1.0, of savings to expenditures means that the development has barely been

* Depreciation computed on the assumption of a 40-yr life for existing locks and dams. Where structures have been replaced, the actual life years were used.

† Columns (23) and (24) for previous year used in formulas for determining figure for Columns (23) and (24).

successful. A higher ratio indicates a profit. In considering these relations between commercial savings and public expenditures, it should not be forgotten that 4% interest has been charged against the entire remaining capital structure for every year. During the depression, railroad companies would have regarded themselves as fortunate, if they were able to pay 4% interest on their entire capital. Fig. 4 shows, in percentage form, the relation between the water-borne commerce and railroad commerce, using the commerce of each during the calendar year 1930 as a base. It can be seen that, after

having been checked for a short time, in 1932 Ohio River commercial traffic recovered. (It is now (1937) more than 50% greater than it was in 1930.) In 1934 traffic of Class I railroads had not reached a figure equal to 75% of its 1930 figures. (It is now (1937) 12% less than in 1930.)

Table 6 has been prepared for the purpose of comparing the data on public savings by an entirely independent system of calculation. The following items supplement the data in Table 6:

(*a*)	Average haul of commodities on Ohio River (1934) in miles	119
(*b*)	Water distance, Cincinnati, Ohio, to Louisville, Ky., in miles	133.5
(*c*)	Total annual charges, 1934 (Column (15), Table 5)	$9 815 249
(*d*)	Total commerce, Ohio River, 1934 (Column (46), Table 4), in ton-miles	1 783 924 624
(*e*)	Government costs, in mills per ton-mile, 1934, $\left(\frac{\text{Item } (c)}{\text{Item } (d)}\right)$	5.5
(*f*)	Government cost plus water cost to shipper (Column (11), Table 6) = total water cost, in mills per ton-mile	14.8
(*g*)	Rail cost to shipper, reflected by quoted rates, in mills per ton-mile (Column (6), Table 6)	21.3
(*h*)	Saving, in mills per ton-mile, by water, on sample ton	6.5

The average haul was determined from the traffic data of the Ohio River, and two important points on the Ohio River (Louisville and Cincinnati) were selected as being about that distance apart. From the official figures of waterborne traffic, the proportion of each significant commodity in a representative ton was ascertained. Based on the rail rates (in carload lots) for these same commodities, it was possible, in the manner shown in Table 6, to determine the rail rate per ton-mile measured by water for a theoretical ton of representative cargo, moving in a carload lot. By similar methods, the water rate per ton-mile was determined for the same unit. Referring to Column (8), Table 6, the rate for coal and coke (Item No. 1) is that quoted by a water carrier. The rail rate on coal is somewhat higher than the average, but a reduction to 8 mills per ton would affect the final values only slightly. The rate for cement (Item No. 2) is that quoted by a water carrier for a 156-mile haul. Item No. 3 (iron and steel, Column (8)) was used in the 1934 study for the 164-mile haul. A large unit rate is used because a short haul is being assumed. The rate for oil and gasoline is that for an 118-mile haul. No terminal differential (see Column (9), Table 6) is assumed because of the more economical river loading. Item No. 5 in Column (10) is the common carrier average on four major commodities. Terminal handling charges are included in this rate. By dividing the annual expenditures by the total ton-mileage (Item (*e*)), the Government cost per ton-mile was also ascertained. As shown, the rail cost was found to be 21.3 mills per ton-mile, and the total combined water cost, 14.8 mills per ton-mile, giving an economic public benefit of 6.5 mills per ton-mile for water-borne traffic. Referring to Table 4, it will be seen, from examination of Column (47) for 1934, that the commercial saving by water on the average cargo was determined as 6.9 mills per ton-mile. The economic public benefit by the methods used in Table 4 would be 6.9 mills, less the Government cost of 5.5 mills, or 1.4 mills. Table 6 thus gives a result about five times as favorable to the waterway as Table 4.

Trends of Commerce

For reasons previously explained, commercial costs for the calendar years 1935 and 1936 have not been included in this study. Since its initiation, however, gross figures for commerce for those years have become available. They indicate an increase in tonnage of 9%, and of ton-mileage of 53 per cent. The greater increase in ton-mileage over tonnage is indicative of a trend which has been evident since 1926. In that year the average haul was 55.7 miles; in 1936, it was 108.7 miles. The reasons are obvious. Long-haul traffic (steel, petroleum products, etc.) has increased. Short-haul traffic, especially sand and gravel, has failed to increase proportionately, or has actually decreased. The increase in ton-mileage over 1934, which may be compared with the 9% increase in ton-mileage in the freight moved on Class I railroads for the same years[18] indicates clearly that, when there is any traffic, the Ohio River gets at least its share, and probably more.

At this point it might be well to take a general view of the commercial figures for the ten years since General Kutz presented his paper. They show clearly what has been noticed before, that no one is able to determine in advance the detailed trends of future commerce on a waterway. In that original study, through steel shipments (that is, steel from the Pittsburgh area to Mississippi River ports) were scarcely of enough importance to receive separate treatment. This movement has now (1937) become the most valuable commerce on the Ohio River; and its value seems destined to increase. More and more manufacturers are sending manufactured steel by water; and there is some evidence of an intent to transfer to the inland route steel which now moves from Pittsburgh to the Coast, and thence to the Gulf, coastwise. The movement of water-borne coal follows the general lines already forecast in 1926, except for the unpredicted activity around Wheeling, W. Va., although here, again, it appears that an industrial depression checks the movement of water-borne coal to a markedly smaller extent than it does rail-borne coal. In General Kutz' paper, the only mention of petroleum is in regard to delivery service from a refinery at Parkersburg, W. Va.[19] Petroleum movement has now become a large item in Ohio River traffic, and shows no signs as yet of approaching a saturation point. On the other hand, the common carrier traffic for which great things were hoped, has not developed proportionately. In spite of modern equipment and excellent management, the common-carrier towboat lines find the transportation of privately owned barges at contract rates absolutely essential for their support.

---

[18] Figures were obtained by comparing those given in Annual Reports of the Interstate Commerce Commission.

[19] *Transactions*, Am. Soc. C. E., Vol. 89 (1926), p. 1121.

The difficulties of common carriers on Western rivers are in considerable part due to the unbalanced character of the tonnage. On an open channel, the most profitable division of tonnage, from a strictly engineering standpoint, is 8 tons of down-stream traffic to 3 tons of up-stream traffic. For the calendar year 1935 the principal common carrier on the Ohio River informs the writer that his ratio was 21 tons down stream to 20 tons up stream. For the same year the report of the Inland Waterways Corporation indicates that, on the Mississippi River, tonnage was 29% down bound and 71% up bound. On the Upper Mississippi section it reached the extraordinary value of 18% down bound to 82% up bound.[20] From a strictly economic standpoint, the obvious remedy is to increase the up-bound rates and to decrease the down-bound rates until the traffic approaches a proper balance. However, a comparatively slight increase in the up-bound rates might divert traffic from the waterway altogether. Similarly, on rail-water movements, a substantial decrease in the down-stream rates might destroy the water carriers' share of the revenue entirely. Until this subject is adequately studied a remedy for the situation is not apparent. It is evident, however, that a profitable common carrier traffic awaits the discovery of the remedy.

The entire trend of Ohio River commerce is toward an increase—often an enormous increase—in the transportation of low-grade, long-haul, bulk products, in which the consumers' savings are only appreciable after a comparatively long period, and after time has been given for competing producers to engage in water transportation. Only to a very small extent have consumers' benefits become apparent in the immediate reduction in the prices of commodities, as a result of their more economical transportation by carriers entirely disinterested in either the manufacture or distribution of the articles transported. It can be asserted with confidence that the waterway reduces, materially, the proportion of the transportation cost contained in the gross cost of articles carried by water, either in their final state, or as raw materials. It is much more difficult to show, and from all indications it will always remain more difficult to show, that the waterway reduces in the same proportion the price which the consumer pays for the manufactured article.

It is evident at any rate that the pessimistic prophecies of 1926 have not proved true. It was then stated[21] by Frank H. Alfred, M. Am. Soc. C. E., that "it does not seem likely, however, that the completion of the improvement project will result in any considerable increase of river traffic." The data in Table 4 certainly prove the contrary.

The Special Board of Engineer Officers, in its report of December 15, 1906, which constitutes the basic plan for the present improvement of the Ohio River, makes a conservative prophecy, which might well be contrasted with the one by Mr. Alfred. The report states that the commercial saving on a 9-ft project with the then existing commerce would amount to $2 280 000 per year; and that "the ultimate annual saving *** would be several times the amount stated."[22] The figures for savings in recent years, Table 4, amount to several times $2 000 000 per year, and thus confirm the far-seeing estimate of 1906.

[21] *Transactions*, Am. Soc. C. E., Vol. 89 (1926), p. 1136.

Non-Statistical Considerations

Some commentators on transportation refer to the regulating effect of an improved waterway on the rates charged by other carriers. The writer has not been able to discover that the existing rail-rate structure discriminates between points having water competition and points that are without water competition.[23] On the other hand, the general rate structure of the Valley appears to be affected by the availability of the canalized Ohio River. One coal operator, not directly interested in water traffic, has recently made the statement that the cost of coal at Cincinnati would be $1.00 per ton higher if there was no river. Although this is mere opinion, it seems to coincide with the general opinion. However, the effect on rates is by no means the only effect of the improved waterway on the population of the region. Routes of communication, banking affiliations, the operations of jobbers, and all the other business relations which characterize the true "regions," in the normal sense of the term, have been built up on the assumption of the existence of the improved waterway. If the river were to disappear the population of the water-shed would begin to diminish with great rapidity. Freight rates, like other costs, would rise with the attenuation of the regional market.

Throughout this study no statistical comparison has been made in regard to passenger traffic. Such traffic is only to a very slight extent commercial. It is essentially travel for pleasure. Yet its general importance to the people of the Valley should not be overlooked. During the season of hot weather, boats of all sizes, from canoes to huge excursion boats, constitute a very important element of joy to the people. None of these boats could operate if the river were not improved.

Conclusions

From both an engineering and an economic standpoint, the canalization of the Ohio River has been successful. This success tends to become greater with time.

APPENDIX

The information in this Appendix supplies confirmatory details for the general information given under the heading "Net Savings."

Coal: Monongahela River to the Ohio River.—The savings per ton-mile for 1934 were 9.7 mills, and for 1925 they were 10.6 mills. As the reduction is believed to have been caused by river-rail movement of coal to Youngstown, Ohio, which was started in 1932, the reduced savings were used for the last two years only.

---

[22] H. R. Doc. No. 492, 60th Cong., 1st Session, p. 36.

[23] A similar conclusion was reached by General Kutz, *Transactions*, Am. Soc. C. E., Vol. 89 (1926), p. 1115.

Coal: From the Kanawha River.—In the absence of more accurate information for 1934, savings of 2.1 mills per ton-mile were used throughout.

Coal: From Huntington, W. Va.—The 1934 savings per ton were calculated as 49 cts, and for 1925 as 40 cts. There has obviously been a progressive increase in the saving on this traffic, and the difference in savings was distributed proportionately throughout the years involved.

Other Coal and Coke.—The 1934 savings were 38 cts per ton, and the 1925 savings were 24 cts per ton. It is reasonably clear that this change was due to an alteration in the character of coal movement. In 1934, 69% of the tonnage was from mines in the vicinity of Wheeling, W. Va., which scarcely produced any water-borne coal in 1926. The savings on the Western Kentucky coal, which is the other principal factor in this category, were very much less than those on the Wheeling coal. The savings were interpolated over the years 1926–1934 according to time. The change in the character of coal traffic has been progressive.

Sand and Gravel.—The savings per ton-mile decreased from 14.9 mills in 1925 to 10 mills in 1934. Apparently, the decrease in savings is due to a decrease in tonnage carried per barge employed. No terminal differential was charged on products moved directly to river points for use in repairing adjacent highways, or for the construction of river improvements, because it is more economical to unload a barge at the site of the work than to unload it from railroad cars, and then haul it in trucks from rail-heads. The decreased value of 10 mills per ton-mile is used throughout the period. Any error in this figure is against the waterway.

Logs and Lumber.—The 1925 savings were 12.2 mills per ton-mile. In 1934, they had decreased to 7 mills per ton-mile. The decrease in savings was adjusted proportionately according to time.

Iron and Steel.—The enormous increase in the savings on iron and steel is obviously due to the great increase in length of haul. In other words, the terminal differential chargeable per ton-mile has been greatly reduced. The saving per ton-mile has been proportioned on the basis of ton-mileage.

Oil and Gasoline.—There is no terminal differential on this product, or, if there is, it is in favor of the waterway. As the average haul increased, the savings per ton-mile were not increased. As up-stream traffic becomes a larger portion of the total haul, the saving per ton-mile decreases. There has been a slight decrease in savings per ton-mile since 1926, due to this latter fact. The decrease has been distributed according to the best information available on the change in character of traffic.

Stone.—On this comparatively small shipment, the figure for saving per ton in 1926 was used throughout.

Cement.—This commodity makes its first appearance at this time as a separate item. The savings, however, were estimated in an unpublished document at 1.9 mills per ton-mile in 1925. In 1934, calculations show the savings at 7.5 mills. The increase is due partly to the fact that no terminal differential is charged on cement delivered to riparian construction projects, and partly to a decided increase in volume of traffic. The savings for the years

1925–1934 have been proportioned on the basis of the ton-miles moved on the river.

Miscellaneous Freight.—The savings per ton increased from 45 cts in 1925 to 66 cts in 1934. The savings per ton-mile decreased from 3.3 to 2.7 mills in the same period. This curious result is due to the increase in the volume of river-rail commerce moving on published rates (with considerably reduced unit savings), combined with a considerable increase in length of haul. The present trend of movement began in 1931. The saving of 3.3 mills is used prior to that year, and the saving of 2.7 mills thereafter.

Terminal Differentials.—The differentials used were determined from the best evidence available. In some cases the sources were confidential. On coal the value generally used was 5 cts per ton for loading, and 15 cts per ton for unloading. On unmanufactured iron and steel it was 15 cts per ton for both loading and unloading. On manufactured steel it was 25 cts per ton for loading and (on an average) 75 cts per ton for unloading. Incidentally, the unloading differential for manufactured iron and steel represents the entire cost of unloading, as the ultimate consignee nearly always takes rail delivery anyway, and, thus, all the cost of unloading from barges is an extra charge. On cement, the loading differential used was 15 cts per ton, and the unloading charge 75 cts per ton (except when it was delivered for use in riparian structures). On freight moved by common carrier, of course, the terminal differential is included in the published rate.

DISCUSSION

Eugene L. Grant,[24] M. Am. Soc. C. E. (by letter).—The author is to be congratulated on his attempt to take the question of the economic justification for a high investment in the improvement of inland waterways out of the realm of conjecture and into the realm of measured facts, and for his careful statement of the assumptions of his study. Likewise, the Corps of Engineers should be commended for its records of river traffic which made possible such a factual study. However, a critical examination of the stated assumptions and of the calculations of Table 5 casts considerable doubt on the expressed conclusion that the Ohio River improvement has been an economic success.

The most important of the assumptions, of course, is Assumption (1) to the effect that all savings are passed on to the public in the form of lower prices. Even under the assumption of free competition of classical economic theory this is not necessarily the case. A saving in transportation costs to all the competing producers in a given industry would be passed on, but a saving to a limited number of producers might or might not be passed on, depending on their competitive positions—that is, on whether or not they are "marginal" producers in the classical economist's sense. Thus, even under free competition it would be likely that a considerable part of the saving in transportation costs from the Ohio River improvement would not be passed on. Under the well-known fixed-price structure of the steel industry, which has been in existence throughout the period of this study, it seems probable that, as far as this industry is concerned, none of the savings has been passed on; there has merely been a transfer of funds from the owners of the railroads that would have carried the traffic, had there been no river improvement, into the pockets of the owners of the steel companies.

With regard to Assumption (2), it may be noted that although the difference between the costs of water transportation and rail rates is a fair measure of the economic advantage to the shipper in instances where the commodity would move by rail if water transportation were not available, this is not the case with traffic that would not move at all if only rail transportation were available. Where traffic is created by the availability of cheap water transportation, the economic advantage to the shipper is the difference between a rate which would just serve to move the traffic (that is, "what the traffic will bear") and the cost of water haul. Although this is not measurable, it constitutes a reason for discounting, somewhat, the author's estimates of savings.

In connection with Assumption (3)—that the savings in the cost of ferriage have been neglected—it might be noted that the increased costs of highway and railway bridges due to the requirements of navigation have also been neglected.

Thus, it appears that the author's carefully stated assumptions favor the waterway to a much greater degree than he has indicated.

Table 5 is an example of a somewhat unconventional method of setting up an engineering economic study. It is in effect a compound amount calculation for all the disbursements and receipts (assuming "annual commercial savings" as receipts), with interest at 4 per cent. Such a calculation with respect to a terminated enterprise would tell whether the invested moneys had been recovered with a 4% return; however, its suitability for judging the economic success of the Ohio River improvement may be questioned.

---

[24] Associate Prof. of Civ. Eng., Stanford Univ., Stanford University, Calif.

This is particularly the case because there are apparently two separate questions which should have been asked: (1) Did the moderate level of improvement of the early days (with \$13 000 000 invested before 1905), pay for itself in reduced transportation costs? and (2) does it appear as if the present canalization of the river (with its investment of \$135 000 000) is likely to pay?

From an inspection of Table 5, the historical picture seems to be somewhat as follows: In 1905, and for a few years thereafter, the investment in river improvement paid handsomely (not as much, however, as is implied by the 266% annual return shown for 1905 and the high returns for the years immediately succeeding; these high values resulted because the author failed to include the \$13 300 000 spent on capital improvements before 1905 as part of the investment on which the return was calculated; he also omitted depreciation on these improvements throughout his study). Then the competition of other forms of transportation apparently resulted in rapid obsolescence of the river improvements, and, by 1919, the commercial savings were barely sufficient to cover operation and maintenance costs, with no allowance for depreciation or return on investment. After this the increasingly high level of river improvement served to stimulate river traffic to the point of increasing the annual commercial savings to more than \$12 000 000 in 1934.

The author's plan of writing off subsequent investments against previous savings, and of assuming an interest income from calculated "surplus," has the tendency to show last year's savings as a return on next year's improvements. It should be clear that this is misleading—that the high commercial savings of the early years which resulted in the "surplus" in the years 1906 to 1912 have no relation at all to the question of whether the subsequent higher level of improvement will prove profitable.

Another objection to the use of the type of calculation involving the determination of a compound amount is the great importance of the assumed interest rate on the apparent conclusion. This dependence of the conclusion on the interest rate assumed is not always obvious either to the engineer making such calculations or to his audience. If, for instance, the author had used 6% as his assumed interest rate, his conclusion would have been that no profit existed in any year after 1915; this would have implied that the high level of improvement of the Ohio River was not an economic success.

The real question with regard to a proposed investment in capital goods—either in private enterprise or in public works—is whether the investment seems likely to be recovered during the economic life of the capital goods plus a return which is attractive in the light of the apparent risks involved. In private enterprise, it is customary not to make such investments unless the prospective rate of return is considerably greater than the cost of money; thus a concern with an average cost of capital of 7% might be likely to require a prospective return of 15% before undertaking a proposed investment. Where the possibility of obsolescence exists, the required safety factor may be much greater; a common requirement in the manufacturing industries is that a proposed investment in cost-reducing machinery must "pay for itself" in two or three years, or, in some cases, in one year.

Two considerations should be noted in connection with interest rates in economy studies regarding public works projects. The first is that when the Government collects taxes it is taking funds which might otherwise be productively invested by the taxpayers. It follows that public works so financed are not socially profitable unless they show capital recovery with a return at least as great as the return from the private investments which are displaced by the diversion of taxpayers' funds to public uses. This is a sound principle even if the difficulties of placing a money value on the benefits from public works make it difficult to calculate a rate of return in many instances; but where benefits are measured, as in the present instance, a project is not economically successful unless the return is as great as the average return obtainable by the investment of capital in private enterprise.

The second consideration in selecting an interest rate for economy studies for public works projects is that of the necessity of a safety factor. The high safety factors commonly used with regard to proposed cost-saving improvements in private enterprise have been mentioned. These safety factors are used because experience has shown that estimates of savings and of the economic lives of capital goods are likely to "go wrong." As errors in such estimates are not confined to private enterprise, it would seem reasonable that a safety factor should also be used in public works projects. This is particularly true in the present case, in which many arbitrary assumptions necessarily enter into the evaluation of benefits. It may also be noted that, although obsolescence does not operate as rapidly in public works as in many private enterprises, the history of the Ohio River navigation presented by the author shows a rapid obsolescence of the earlier moderate level of improvement.

The use of a 4% interest rate in this economy study is in effect the assumption that 4% is a satisfactory return on the Government's investment in the Ohio River improvement. In the light of the considerations which have just been mentioned it would seem as if the return should be considerably higher than this, before it can be said that the improvement has been economically justified.

For this reason it should be of interest to determine the apparent rate of return in each of the thirty years of record, making calculations which avoid any interest charges or any assumed interest rate. At first glance, it might appear that Column (20) of Table 5, gives the excess above, or deficiency below, a 4% return. This is not the case, however, because of the author's neglect of the investment prior to 1905 and because of the fact that the interest charge or credit has been based on the "cumulated capital account" rather than on the depreciated investment. Therefore, the writer has computed, in Table 7, the apparent profit or loss that would have been shown each year in the income statement of a private enterprise with receipts equal to the commercial savings of Column (16), Table 5, and operation and maintenance costs equal to the values shown in Column (7). In the absence of any information regarding the dates of the $13 000 000 investment prior to 1905, the depreciated investment at the beginning of 1905 has been assumed arbitrarily as $10 000 000 and depreciation has been charged on the investment on the basis of an assumed 40-yr life; the annual depreciation charges shown in Column (14), Table 5, are thus increased by $250 000. All values have been expressed to the nearest $10 000, as it does not seem that more significant places are justified by the character of the available data.

The record as shown from 1912 to 1934 in Column (5), Table 7, is not impressive; the rate of return is never great enough to be considered attractive in the light of the risks involved. It will be noted that this is so despite the fact that Table 7 gives the waterway considerably more than it is entitled to by assuming the revenue as 100% of the author's estimate of commercial savings. If, as suggested at the beginning of this discussion, much of the savings in transportation costs are not passed on to the public in the form of reduced prices, the "picture" becomes even more unfavorable to the waterway. For instance, if it is assumed that only 50% of the savings are passed on, there has been no profit in twenty-two of the last twenty-three years. It would seem, therefore, that even if weight is given to the "Non-Statistical Considerations" noted at the end of the paper, the Ohio River improvement can scarcely be considered an economic success.

TABLE 7.—ANNUAL PROFIT AND LOSS STATEMENT (IN MILLIONS OF DOLLARS) AND RATE OF RETURN ON DEPRECIATED INVESTMENT FOR OHIO RIVER IMPROVEMENT

FRED LAVIS,[25] M. AM. SOC. C. E. (by letter).—The members of the Society are to be congratulated on the paper by Colonel Hall and the very illuminating data he has presented in regard to transportation on the Ohio River and the costs thereof. They are an important addition to the available data on this subject.

---

[25] Cons. Engr., New York, N. Y.

There are two points to be noted, however: First, his assumption that Government expenditures in the case of the improvements on the Ohio River are in the same class with those for ocean terminals and lighthouse service; and, second, that comparisons of costs of transportation between line terminals are a true criterion of comparison between rail and water-borne transportation.

The comparison with the provision of land beacons for the guidance of airplanes, while perhaps partly apropos, is not entirely so, because these beacons have to do with the carrying of the mails and the need of national defense to keep abreast of other nations in the development of aviation. They are also a necessary service for the actual military needs of to-day.

Improvements of harbors on the coast at the expense of the nation are justified because they affect the entire life of the nation and its people, unless they believe in, and can actually practice, an isolationist policy—which they neither do nor can. The coast line and harbors of the United States are the concern of the nation as a whole, not merely of those who live next to them, and, therefore, must be a charge against the Federal Government.

To take only two specific examples: The coffee on practically every breakfast table in the country, every morning, whether it be New York, Ohio, Virginia, Colorado, or anywhere else, must come in through an ocean terminal port. Automobiles made in Detroit, Mich., for export must be shipped out through an ocean terminal, etc. Ocean terminals really serve a national use.

It is quite understandable also that the lower reaches of some rivers can be included as part of the coast line, or as parts of, or extensions to, maritime harbors. The exact line of demarcation between coast line and inland waterways may be difficult to determine. Notwithstanding the long established legal authority of the Federal Government over all "navigable" waterways, it is difficult, however, to consider such improvements as those of the Ohio River other than local improvements or as beneficial to other than local interests. Colonel Hall's paper tends to confirm this.

Of course, the writer is not unmindful of the possible far-reaching effects of flood control, but that hardly affects the present discussion.

Comparisons of transportation costs between main line termini are not of much value; neither are ton-mile costs *per se* inasmuch as the river is almost sure to be longer than a parallel line of land transportation. The true criterion is the cost of transportation from producer to consumer. If coal is produced at a mine on the river, shot directly into barges, transported, and then consumed at another point on the river after direct transfer from barge to firebox, the river charge is an accurate measure of the cost of transportation, provided *pro rata* costs of construction and maintenance of river facilities are included.

Colonel Hall's paper indicates that these last named costs are not included, and he thinks their payment by the general public is offset by general public benefits. It is difficult to follow this reasoning, or to understand why a taxpayer in Portland, Me., Boston, Mass., New York, N. Y., Seattle, Wash., or San Francisco, Calif., should pay for these local benefits to people who happen to live alongside the improved channel of the Ohio River.

There is also to be considered the very strict regulation of rail rates and the limitation of return by Federal agencies on investments in railways which takes no account of this subsidized competition.

Leaving this subject, there still remains the question as to whether river costs (including the cost of the improvement) between termini are true measures of the transportation costs of the material carried on the river. Much of this material, it would seem, must have further charges for land transportation at either or both ends. A true comparison, therefore, can only be made by comparing all transportation charges, including loading and unloading en route, if any, between producer and consumer.

For any bulk freight such as that handled by river, this may be an important consideration. It might well be that the actual full cost of transportation of coal between off-river points might be less if it were handled from a railroad siding at a mine to a railroad siding in the plant where it is finally consumed.

There seems to be little doubt that the improvements on the Ohio River benefit somebody and provide low costs of transportation on some goods for some people. It does not, however, seem to be apparent from this paper, or from other available evidence, that this justifies taxation of others whose benefits are very small, or nothing at all. Moreover, the mere comparison of costs between main-line termini by one or more different methods of transportation is not a true measure of comparison of transportation costs.

O. Slack Barrett,[26] Esq. (by letter).—Complete and convincing as this paper seems to be, a careful study reveals the need of emphasis on several aspects of it.

History of the Ohio Valley Improvement.—Although the first dam was completed at Davis Island, in 1884 (as Colonel Hall states) there was no real canalization until years after 1895 when The Ohio Valley Improvement Association was organized. By the time the Panama Canal was opened to commercial navigation in August, 1914, only twelve dams had been completed on the Ohio River, and most of those between 1910 and 1914. The sum and substance of the matter is that these dams were located and built to facilitate navigation over some of the worst parts of the river, and served principally to expedite coal movements from Pennsylvania and West Virginia mines to markets, some of which were in the deep South. Even then, it will be noted, two factors seem to have been the motivating considerations, namely, cheaper transportation and wider markets.

In 1914, the war in Europe began at about the same time that navigation was opened in the Panama Canal. It is impossible to separate the effects of these two simultaneous events, but the four years of war demonstrated the necessity of adequate transportation facilities, and the Panama Canal, by shortening the commercial distance between the two coasts, increased the disadvantages suffered by industries in these inland valleys in competition with those situated at tide-water. The result was the popular demand for the completion of the improvement of the Ohio River, deepening and stabilizing channels in the Mississippi River, and the improvement of other waterways.

---

[26] Pres., Ohio Valley Improvement Assoc., Cincinnati, Ohio.

About ten years after the close of the World War, and fifteen years after the opening of the Panama Canal, the canalized Ohio River was open for continuous navigation. In the mean time, oil had largely replaced coal in the Southern markets, and what was left of the coal movement amounted to a number of important isolated trades. It is significant, however, that the prospect of dependable channels in the Ohio and Mississippi Rivers attracted the attention of alert industrial managers to such an extent that the 1929 traffic (not counting that of the tributaries) amounted to 1 513 000 000 ton-miles, with coal accounting for 50%, and the growing iron and steel traffic accounting for about 27 per cent.

The year, 1929, will long be remembered as the beginning of the great depression. By 1932, the traffic decreased to 1 392 000 000 ton-miles, but in 1933, with the resumption of industrial activity in the United States, the traffic began to mount until 1936 when it attained 2 653 000 000 ton-miles, representing an increase of 75.5% over the traffic in 1929, with iron and steel accounting for almost 34 per cent.

Benefits.—Colonel Hall has definitely shown, by detailed figures, the most authoritative estimate of the actual savings afforded by the present use of the improved Ohio River. This might be considered as the direct public benefit. There has been some speculation as to whether the savings are enjoyed by the consumer or by the producer, by the shipper or by the consignee. Such speculation is interesting from an academic viewpoint as an effort to determine what part of the public derives the benefit. In fact, both the producer or the shipper and the consumer or the consignee are the public, and any benefits derived by either or by both are derived by the public.

In addition, there are the indirect benefits merely suggested in several places in the paper. These benefits cannot be measured, charted, and definitely analyzed, but they probably constitute the greater part of the economic value of the improvement. It has been freely admitted that the great steel industry could not exist in the United States without cheap water transportation. It is certain that the Pittsburgh industrial area is dependent upon it. No man would hazard the suggestion that the public is not benefited by such industrial activity. What public-spirited citizen of large vision would advocate concentration of all the major industrial plants on the seaboard? The improved Ohio River is a large contributing factor in retaining and attracting industry, thus contributing to a more balanced development of the nation.

It is a definitely established fact that the rate structure applicable to commodities which form the bulk of the freight on the rivers has been substantially lowered. The best evidence on this point can be found in the rates approved by the Interstate Commerce Commission in the last decade. The freight bill paid by citizens has been lowered substantially.

The net result of the improvement of the Ohio and Mississippi Rivers is that the purchaser has been able to buy, and the seller to sell, in wider markets. More opportunities have been afforded both buyer and seller, all to the direct and indirect benefit of the citizens of the nation. The benefits are increasing with the growing use of the river. These were the ends on which the improvement was predicated.

Edmund L. Daley,[27] **M. Am. Soc. C. E., and Forrest E. Byrns,**[28] **Assoc. M. Am. Soc. C. E.** (by letter).—Too often the discussion of the economics of river improvements reaches one of two fallacious conclusions:

(*a*) Internal waterways are anachronistic. They have outlived their usefulness in the development of the country. Their further improvement by the United States is, in all cases, a waste of Federal funds.

(*b*) Improved waterways constitute the panacea of all transportation ills. They provide the minimum in transportation costs and, in addition to the savings procured to the public through shipments over the waterways themselves, they have a beneficial effect on the rates charged by all other carriers.

Colonel Hall avoids either extreme position. Dispassionately, he has analyzed the economic factors involved in modern transportation on one particular waterway.

In a study of the Ohio River, derivation of tangible benefits is made easier because of the abundance of accurate data on the volume and types of river traffic. As in all studies of this kind, the greatest difficulty lies in determining the actual transportation costs to the shippers. The author follows a logical method of analyzing the complicated economic questions which must be considered.

All rivers are not worthy of improvement. Some rivers do have characteristics which constitute a *prima facie* case for economic river transportation. In the present day, river transportation is most useful in the movement of bulk commodities originating at points lying close to the river route and destined for points also close to the waterway. The Ohio River is especially well situated for manufacturers and shippers to take advantage of this condition.

Bulk commodities, such as coal and coke, iron and steel, oil and gasoline, stone, sand, and gravel, and cement, originate on or near the main river or its tributaries and move at low costs to points on or close to the river or connecting waterways. This is a natural and proper utilization of this national asset.

Colonel Hall analyzes the public benefits resulting from these low shipping costs. He limits the analysis to a discussion of transportation differentials and makes a careful comparison of the entire cost of the waterway shipping (including construction costs) with rail shipping. He finds that the total cost of water shipments on the Ohio River at the present time is less than the cost of rail shipments. In the past few years, traffic on the river has been increasing. The present trend indicates that both the tonnage and, more particularly, the ton-mileage will continue to increase. The conclusion reached is that from both an engineering and an economic standpoint, the canalization of the Ohio River has been successful and that this success tends to become greater with time.

The author is to be commended for the definite statement and discussion of the assumptions upon which much of his cost study is based. The most vulnerable point for criticism of this or any similar study is his Assumption (1). This is tacitly admitted by Colonel Hall, as well as the fact that any error in the assumption favors the waterway. An attempt in each individual case to determine the exact percentage of savings due to water shipments that is passed on to the public is clearly an impossibility. That the percentage is high and that, as Colonel Hall states, with the continued increase in the use of the waterway and the resulting keener competition, this percentage will continue to increase until eventually the original assumption will become accurate, is undoubtedly true.

[27] Col., Corps of Engrs., U. S. Army; Div. Engr., North Atlantic Div., New York, N. Y.

[28] Engr., U. S. Engr. Office, North Atlantic Div., War Dept., New York, N. Y.

Presumably, opponents of river improvement will grant that as far as the Ohio River is concerned, if these computed definite actual benefits are in error, at least the error is not great enough to change the results very much in the other direction. Then one comes to the consideration of other intangible public benefits that are difficult of assessment. Although these intangible benefits were not considered by Colonel Hall, they are very real.

Up to the time of the Civil War, traffic that was moved for any distance was largely water-borne. The development of the United States, and the extension of its settlement from the eastern seaboard, followed naturally along the navigable waters. Many of the early canals and early river improvements that were in themselves largely unprofitable were warranted by the development of the country which resulted from them.

Since the Civil War, the transportation picture has changed. As canalboats were displaced by railroads and other more rapid means of transportation, commercial navigation on rivers and canals gradually assumed less and less importance.

Before this, due to the advantage of low-cost water transportation of bulk commodities, new basic industries had arisen. Large towns and cities had been built around these and related industries, with consequent economic benefit to the Federal and State Governments. Railroads have partaken of these benefits by reason of the high tariff freight which has been developed from new communities, such as Clairton, Aliquippa, and Ambridge, Pa., and Weirton and Follansbee, W. Va. These are very large benefits. New wealth was created. The monetary value of these benefits is positive but not definitely calculable.

Within the past few years manufacturers and shippers have begun to rediscover the advantages of shipping on the inland waterways. New equipment is being developed for the transportation of bulk commodities. Barges and self-propelled motor ships (especially tankers) are being designed particularly to fit the conditions existing on the more important inland waterways.

Time only will tell definitely whether the more recent improvements on the rivers of the United States, involving the expenditure of many millions of dollars, are in all cases economically justified. Colonel Hall's paper shows that the present commerce on the Ohio River and the resultant savings in transportation costs justify the large expenditures made for its improvement.

J. E. WILLOUGHBY[29] AND W. D. FAUCETTE,[30] MEMBERS, AM. SOC. C. E. (by letter).—The problem offered for discussion in this paper is stated by the author as follows (see heading: "The Problem"):

"Freight moves on the Ohio River because it can be transported more cheaply by water carriers than by land carriers. It can be transported at low rates because engineering works have been built on the river at the expense of the taxpayer. Since no tolls are charged, the Treasury derives no direct return. The public obtains an indirect return in the reduced net cost of water-transported articles consumed. The problem is to compare the engineering costs of the improvement with the value of the public benefits. * * *"

---

[29] Chf. Engr., A. C. L. R. R., Wilmington, N. C.

[30] Chf. Engr., S. A. L. Ry. System, Norfolk, Va.

Assumption (1) is that the entire reduction of costs (the author means, not all the cost, but merely the boat operator's cost) in transportation of freight, due to the existence of an improved waterway on the Ohio River, is passed on to the public in the form of lower prices of the goods transported, and hence becomes a public saving.

His own discussion which follows indicates that this is a most violent assumption. In the report of the Mississippi Valley Committee of the Public Works Administration (PWA), submitted to Administrator Ickes on October 1, 1934, it was correctly stated: "Private carriers—largely coal and steel companies—now transport more than 95% of the total commerce on the Ohio River." Recently, there has developed a heavy volume of petroleum products moved in tank barges for the large oil companies.

As Fig. 1 shows, the really heavy tonnage of coal on the Ohio River is between Huntington, W. Va. (*via* the Kanawha River or by rail) and Cincinnati, Ohio, where some of it is re-shipped by rail. The author quotes testimony indicating that any difference between the rail-river-rail and all-rail costs is not passed on to the consumer, but that the cost to the consumer is identically the same. The writers know of other evidence before the Interstate Commerce Commission indicating that all such coal is sold on the basis of the all-rail rates. The great bulk of the coal consumed along the Ohio River and contiguous territory is moved by all-rail routes, and it may safely be stated that in the great majority of instances any alleged "saving" is simply "pocketed" by the seller.

It is well known that iron and steel, moving in heavy volume the length of the Ohio River, are generally sold on the basis of certain mill prices (usually Pittsburgh) plus the rail rates from there to their destinations. The alleged "saving" is retained by the shipper or producer.

It is certain that the price of gasoline to the consumer is not less because of the heavy volume of water-borne gasoline on the Ohio River. It is a matter of common knowledge that these prices closely reflect the price in the Mid-Continent Field plus the cost (usually rail rate) of transporting it to its destination.

It is useless to consider sand and gravel, moving in heavy volume by barge, because the value of river improvements and maintenance to such traffic is nil, if not a detriment.

Assumption (2) is that the reduction of cost in transportation of freight is equal to the rail cost of transporting the freight actually carried by water, minus the water cost of transporting that same freight.

The author complains because rail costs cannot be determined, and it is necessary, therefore, to use rail rates; but water rates are as difficult to determine as rail costs and, therefore, it is necessary to compare rail rates with water costs. In doing so, however, it must be obvious that like is not compared with like. As will be developed later the author's alleged "water costs" are nothing more than general averages plus so-called "terminal differentials" and there are available general averages of rail charges in the form of average ton-mile earnings which would have permitted of like-for-like comparisons.

The author's definition of cost in Assumption (2) is subject to criticism. Assumption (3) requires no comment, and Assumption (4) is admittedly incorrect. It is possible to obtain a break-down of the expenditures of the Federal Lighthouse Service and of the Steamboat Inspection Service sufficient even to approximate the costs chargeable to the Ohio River. Whatever they are, large or small, they should be included to secure the true picture.

Assumption (5) is that, in comparing expenditures and benefits, no allowance has been made for taxes. This is correct; but why not? One reason assigned by the author is that such a charge is not applied generally to all carriers moving on public highways. Although it may be true that motor carriers do not pay adequately for the use of the public highways, they do pay something for such use in the form of special gasoline or mileage taxes, whereas the water carriers pay nothing. Another assigned reason is that nobody charges the cost of lighting an airway against an air line. This is an irrelevant statement when the purpose is to compare rail costs with water costs.

He then argues that the water carriers pay taxes on terminal properties which would have practically no value if the waterways were not improved. Perhaps this is true, but he ignores the fact that such water terminal properties generally take the place of railroad terminal properties which are just as taxable. Then he states that they pay taxes on floating plants that would not exist if there were no waterways. Here, again, he ignores the fact that the floating plant takes out of commission, at the very least, an equivalent in railroad equipment which is taxable. The fact is that most of the water carriers incorporate in Delaware and thereby escape the payment of taxes anywhere on floating equipment. (In this connection see reports of the Mississippi Valley Barge Line Company and American Barge Line Company on file with the Interstate Commerce Commission.)

Furthermore, when the tax-free, improved, Ohio River waterway and the virtually tax-free barge companies operating over it engage in competition with the tax-paying railroads (paying in taxes approximately 7 cts of each gross revenue dollar), the result is not only to decrease the railroad volume and increase its unit costs, but it lessens the ability of the railroad to pay taxes needed for Government purposes, including public schools. The tax revenue loss thus created must of necessity be made up by heavier taxation on other property owners and taxpayers, as has been so well stated by Professor H. L. Lutz in "Public Finance," who stated further that the exemption of a utility from taxation means an exemption of the users of the service from taxation, to the extent of their use. In the present case, it means that a relatively few large steel, coal, and petroleum companies transporting 95% of the traffic on the Ohio River are receiving the benefit while the general taxpayers are paying the deficit. As bearing on taxes, the following quotation from Professor Lutz is apt:

"There appear to be good reasons for the inclusion of a charge against current earnings roughly equivalent to the local tax on a similar private property. In the first place, such a charge is a proper element of cost which the industry should bear, whether it is publicly or privately operated. Secondly, the imposition of such a charge would throw into clearer relief the actual incidence of the benefits of public as compared with private operation. It is not desirable in a democratic community that any limited class should continue to receive benefits which are being paid for by the remainder of the group, unless this class is defective in intelligence and earning power, or is subject to handicaps of health and strength which require special acknowledgment. A third reason for the inclusion of such a tax charge is found in the fact that by such a practice some part of the cost of government is diffused among those who are not readily reached by means of property taxes or other direct forms of revenue."

It is true that taxes are not actually paid on the improved waterway and scant taxes are paid by the boat operators; but when, from an economic and social standpoint, an attempt is made to measure the relative economics of waterway *versus* rail transportation, an allowance for taxes must be made, either by adding them to the waterway costs or by deducting them from the rail costs. Simply to ignore taxes as is done by the author is untenable.

Referring to that part of the paper headed "Carrier Costs of Water-Borne Freight": The basis for the approximate costs, as stated, is somewhat obscure. There is no way for the writers to check any of the alleged "savings," in cents per ton, or in thousands of dollars, appearing in Table 3. For the purpose of analysis the writers will have to be content to use the "line-haul costs of 2 and 3 mills per ton-mile for principal coal movements, and about 3 mills per ton-mile for steel." Although the so-called "terminal differentials" generally used by the author are stated at the end of the paper, it is difficult to make use of them, so they are largely disregarded herein.

In discussing Table 4, the author admits the overwhelming importance of the four products, coal, steel, petroleum, and sand and gravel.

Under the heading, "Net Savings," the author states that the costs on each of the more commonly used routes for each important commodity were determined by multiplying the ton-mileage moved by the average cost per ton-mile as estimated (for water-borne freight), adding the terminal differential between rail and water transfers (except petroleum), and also adding the actual rate for rail haul where the commodity was hauled either to the river, from the river, or both; these costs were deducted from the comparative rail rates, and the gross savings established, and from this value the savings per ton-mile were obtained.

Solely for the purpose of discussion, the writers accept the Government costs, in mills per ton-mile (1934), of 5.6 as stated. This is a water ton-mile cost to the Government. It is conservative to state that, due to the meandering of the inland rivers, the water distance, except for railways that follow the meandering river, is on the average at least 50% longer than the short-rail distance. It is perhaps true that the average movement by rail may be as much as 10% (the former Federal Co-Ordinator computed it at 11%) longer than the shortest route. Consequently, to obtain a fair comparison of water-line costs (Government and boat operator) per ton-mile with rail revenues per ton-mile, the former must be inflated 50% and the latter 10%, thus bringing both to a short rail-mile basis.

In this connection, it should again be stated that sand and gravel, now and long before the present improvements, is and was dredged from near-by sand bars and moves short distances to large cities. By no stretch of the imagination can sand and gravel secure a material benefit, if any at all, from the costly river improvements and maintenance. It has been said, truthfully, that the pools formed by the forty-nine dams in the Ohio River submerge and otherwise destroy (by failure to create) sand-bars from which the sand and gravel is dredged; and yet, the cost of the river improvements and maintenance is spread over all traffic, including this heavy tonnage of sand and gravel. Table 4 shows that of the total of 13 018 335 000 ton-miles in 1934, 1 026 849 000 ton-miles were represented by sand and gravel. It is likewise doubtful whether the improvements and maintenance were of any value to the log and lumber traffic, the ton-miles of which in 1934 were 64 516 000. Sand, gravel, logs, and lumber represented more than 8% of the total ton-miles. If eliminated, and if the Government cost were allocated to the traffic that benefits therefrom, obviously, the average Government cost would be in excess of 5.6 mills per water ton-mile. For the purpose of comparison, however, 5.6 mills will be used.

Although it is stated that the average Ohio River haul is 119 miles, clearly this is depressed because of the influence of the short-haul sand and gravel traffic. In any event, it is not a very important factor in this analysis.

The rail carriers that are principally competitive with the traffic moving over the Ohio River waterway, together with ton-mile revenues in 1934, actual and as inflated 10% to make them fairly comparable with absolute short-rail hauls, are as shown in Table 8.

TABLE 8.—REVENUES FOR RAIL HAUL FOR 1934

Railroad	REVENUES, IN MILLS PER TON-MILE	
	Actual	Inflated 10%
Chesapeake and Ohio	5.96	6.56
Norfolk and Western	6.62	7.28
Louisville and Nashville	8.18	9.00
Pennsylvania	9.15	10.06
Baltimore and Ohio	9.46	10.41

TABLE 9.—WATER TON-MILE COST

Operator	RATE, IN MILLS PER TON-MILE	
	Actual water ton-mile	Equivalent rail ton-mile
Government	5.6	8.4
Water operator	2.0	3.0
Total (water cost, 2¢)	7.6	11.4
Government	5.6	8.4
Water operator	3.0	4.5
Total (water cost, 3¢)	8.6	12.9

Each of these carriers transports a heavy volume of the same bulk commodities as are transported on the Ohio River, principally coal. Out of these earnings they must pay all costs, including taxes. With the exception of the Baltimore and Ohio Railroad all were prosperous, or fairly so. No one can deny that for comparative purposes they represent a fair selection to determine the relative true costs of moving traffic on the Ohio River compared with railroad haulage.

Ignoring entirely any factor of excess terminal costs of waterway over rail, and the exemption of water transportation from taxes, and merely using the average of 5.6 mills per water ton-mile, Government cost (also as inflated 50% to reflect an equivalent rail ton-mile) and water operator costs of both 2 and 3 cts (see heading, "Carrier Costs of Water-Borne Freight") per water ton-mile (also as inflated), the values shown in Table 9 result.

It will be observed that these partial waterway costs are greatly in excess of any of the foregoing rail lines. If average ton-mile costs are to be used for water transportation then it is eminently fair to use average ton-mile revenues for the railways; in fact, their use is decidedly favorable to the waterway transportation.

Fig. 1 shows a heavy tonnage of coal between Huntington and Cincinnati. This coal originates on the Chesapeake and Ohio Railway which line has established very low rates to Huntington for the movement beyond that point *via* river; it is unloaded through a tipple into barges at Huntington. Most of the coal then moves to a point just west of Cincinnati where it is unloaded, moved up an incline through a tipple and dumped into rail cars for movement to points in and about Cincinnati and points beyond. It is obvious that the barge movement between Huntington and Cincinnati is simply a substitute for Chesapeake and Ohio rail service between the same points. The Chesapeake and Ohio runs parallel to the Ohio River between these points, and both the river and the railroad are about 160 miles long. Movement *via* barge necessitates two intermediate terminal services which are avoided on all-rail movements.

Computing the barge movement at 2 mills per ton-mile, a low estimate (see author's discussion of Table 3), and loading at Huntington at 5 cts per ton, unloading at Cincinnati at 15 cts per ton (see "Terminal Differentials"), plus the Government cost of 5.6 mills per ton-mile, the total cost for 160 miles is $1.42 per ton.

The average ton-mile revenue of the Chesapeake and Ohio Railroad in 1934 was 5.96 mills. This includes all terminal expenses. This railroad had an average haul in 1934 of 284 miles. Although the substitute haul, in this case, is less, no additional origin terminal expense would have been necessary if handled through by the road, and the same would have been true if the coal had been consigned to points beyond Cincinnati. The average of 5.96 is conservative. It produces 95 cts per ton for the rail haul from Huntington to Cincinnati, as contrasted with a total cost of $1.42 per ton for the substitute river service. Manifestly, a movement *via* river is profitable to the transporter only because the taxpayers through the Federal Government contribute 90 cts of the true cost of such a movement.

It is probable that the alleged savings as determined by the author (Table 4) would not stand the test if it were possible to check his computations. In this connection note Table 6 and the author's discussion of Table 6. What he does here is to assume movements from Cincinnati proper to Louisville, Ky., proper (note this carefully) of:

Freight	Movement, in thousands of tons	Equivalent movement, in millions of ton-miles
Coal and coke	10 805	741
Cement	108	21
Iron and steel	844	473
Oil and gasoline	1 272	201
Unclassified	939	288

He then proceeds to determine the rail costs to a shipper per water ton-mile by using the local rail rates from Cincinnati to Louisville as contrasted with an assumed water cost per water ton-mile. A local rail movement of coal from Cincinnati to Louisville is almost impossible. No coal originates there and the rail rate used is virtually meaningless. The fictitious rail movement used represents nearly 50% of the total ton-miles used in the comparison, and greatly affects the showing. There is little likelihood of any appreciable movement of cement or iron and steel either by rail or by water locally, from Cincinnati to Louisville. The entire comparison partakes of the nature of aligning data in a direction favorable to the project and to produce a desired result.

By the method used, the author is able to produce an average rail cost to the shipper on the aforementioned traffic from Cincinnati to Louisville of 21.3 mills per water ton-mile as contrasted with a water cost of 14.9 mills per water ton-mile (cost to shipper 9.3 mills plus cost to Government 5.6 mills), and yet the average ton-mile earnings of the Louisville and Nashville Railroad Company and the Baltimore and Ohio Railroad Company (also operating between Cincinnati and Louisville) were only 8.18 and 9.46 mills, respectively.

Under the heading, "Non-Statistical Considerations," the author apparently attaches much value "to the regulating effect of an improved waterway on the rates charged by other carriers." This can only be predicated on an Interstate Commerce Commission so impotent as to permit rail carriers to maintain rates higher than are just and reasonable. Although it is true that, in many cases, water competition has depressed the rates of the rail lines, it must not be overlooked that: An efficient railway system serves the entire country; it serves points on the rivers as well as in the interior; it must have operating revenues sufficient to pay all expenses, taxes, and a reasonable return on investment; the people as a whole must of necessity support the railway plant by paying rates that will produce sufficient revenues in the aggregate; and that were it not for the necessity of reducing some rail rates to meet subsidized water competition which benefits a relatively small part of the general public, the transportation burden might be more equitably distributed. The writers cannot agree that the so-called "regulating effect of an improved waterway" furnishes any economic justification for the huge expenditures of the taxpayers on waterways. No Government function, on one hand, should assume that another Government agency is not alive to its duties.

If the author had chosen to balance alleged benefits of this kind against disadvantages, he might have mentioned the facts that: The 49 dams have created a series of 49 pools, or lakes, averaging 20 miles in length; in periods of slack-water the current is almost negligible; the sewage dumped in the river at the numerous large cities has made the Ohio almost an open sewer, with a stench so bad in summer as to be noticeable, and even chemicals cannot destroy the bad taste of the city water at such periods; and, due to these virtually stagnant pools, all the large cities along the Ohio River must eventually install sewage disposal plants at heavy cost.

W. E. R. Covell,[31] M. Am. Soc. C. E. (by letter).—An analysis of the economics of the Ohio River improvement was presented by C. W. Kutz,[32] M. Am. Soc. C. E., in 1926, who covered the period from 1905 to 1925, inclusive. It is true that improvements have been made in the collection of commercial statistics, which afford more complete data with respect to the movements of river commerce from origin to destination. However, intimate knowledge of the sources and treatment of the data which were presented in the initial paper, particularly with respect to the upper end of the Ohio River and its principal commercial head-water, the Monongahela River, with their long history of heavy traffic, lead to the belief that the economic status of the Ohio River improvement to the end of 1925, as accepted from General Kutz's paper, is reasonably adequate. Colonel Hall's paper, therefore, makes available a complete although composite analysis of the economics of the Ohio River improvement up to and including the calendar year 1934.

The author's economic analysis is predicated upon five basic assumptions, which he lists and discusses in the section dealing with this feature. It is believed that all the assumptions as made are tenable.

Under Assumption (1) it is considered that the entire reduction of costs in transportation of freight is eventually passed on to the consumer. A particular function of the Ohio River improvement is that it broadens and intensifies competition with respect to industries, such as iron and steel, situated both on the water and inland, with a favorable effect upon the prices the public must pay for the products of such industries. The general public also benefits directly in many other ways; for example, many electric utilities are situated on the river and receive their fuel supply *via* water. The cheaper cost of coal is reflected in cheaper rates to the consumers of electricity.

The river improvements have exerted a regulatory effect upon the rail-rate structure for coal in the Ohio River Basin by inhibiting a tendency toward higher prices. In this manner the savings in transportation effected by water are at least indirectly realized by the general public. General Kutz stated that his investigation indicated that, in general, the rail-rate structure for coal and steel movements in the Ohio River Basin did not discriminate between points having water competition and those without such competition. Nevertheless, certain exceptions were noted which are still applicable. Short-haul rail rates on coal in the region at the head of the Ohio River where coal movements on the rivers are very large, appear to be considerably less in the valleys where there is water competition than in the valleys without river improvements.

As indicated by the author in his discussion of Assumption (2), to present a rational analysis of the economics of the Ohio River improvement it is necessary to resort to rail rates as the basis for determining transportation savings by water. As long as the comparison is made completely from origin to destination (that is, not limited to line haul alone), the method serves the purpose adequately and, it is believed, equitably.

---

[31] Lt.-Col., Corps of Engrs., U. S. Army; Dist. Engr., U. S. Engr. Office, Pittsburgh, Pa.

[32] "The Relation of the Ohio River and Its Tributaries to Transportation in the United States," by C. W. Kutz, *Transactions*, Am. Soc. C. E., Vol. 89 (1926), pp. 1106–1122.

The following difficulties attending the river-rail comparison may be cited: For long hauls involving the Ohio River, the rail distance between origin and destination is usually shorter, as stated by General Kutz in his paper. Moreover, more than one rail line or system may afford the same service, a matter which has a bearing upon capital investment in railroad facilities underlying the service. Undoubtedly, the revenue from the relatively high short-haul rail rates goes in some part toward making up possible deficiencies in revenue from long-haul rail service. The statement is also often made that a railroad system has no concern over the fact that the rates for certain short hauls may be practically the same as for much longer hauls, which may place certain areas at a competitive disadvantage with others. The average rail revenue per ton for the system is what counts. However, resort to average rail rates is manifestly not equitable in the comparison of the cost of the competing transportation services for the derivation of the savings, since only the rail rates applicable represent actual "out-of-pocket" costs to the shipper for the rail service between origin and destination.

The transportation savings as determined do not include those resulting from temporary or emergency freight rates which, during several recent years, were appreciable. The Association of American Railroads has petitioned the Interstate Commerce Commission for a flat increase of 15% in rail freight rates throughout the United States. If this increase or any substantial part of it should finally be granted, as seems possible at the present time, due to the financial straits of several of the railroad systems, a very material increase in mills per ton-mile will apply to the savings for the future Ohio River commerce even if the cost of haul on the Ohio River were also to increase as much as 15 per cent.

In Assumptions (3) and (4) Colonel Hall deals with general ferry traffic and the capital cost of the Ohio River improvement, respectively. The Ohio River, in the calendar year 1935, accounted for 1 160 639 tons of general ferry traffic; in 1936, such traffic mounted to 1 309 405 tons. Canalization of the Ohio River has permitted this traffic to be handled more safely and expediently. Although it is difficult to place a value on these benefits, they are positive and constitute a credit to the waterway improvement, which has not been included in the economic analysis. It is believed that there is no particular point in attempting to estimate and charge the waterway with the costs of the Federal Lighthouse Service and Steamboat Inspection Service on the Ohio River, since the costs are comparatively nominal.

Assumption (5) is as follows: "In comparing expenditures and benefits, no allowance has been made for taxes." This means that although the rail rates reflect taxes on the capital investment in railroad facilities, the Federal investment in the Ohio River improvement is not subjected to an equivalent charge in the economic analysis. There is some room for difference of opinion on this score. The basic question is whether or not the Federal Government would have been further ahead had the same funds gone into private investment on which taxes would accrue to the Government. It is believed that an investment of the Ohio River type does not necessarily result in a reduction of private investment of like amount. The improvement of the Ohio River has resulted through a subsidy on the part of the Federal Government to the Ohio River Valley which is rich in natural resources. The Federal Government, in its paternalistic attitude, has fostered the development of the Ohio Valley to such a degree that the river improvement has become a national asset. Every large city in the country is located on a navigable waterway. It is believed that the return in taxes resulting from the development of the Ohio River Valley made possible by the improvement of the river far outweighs any possible loss in taxes occasioned by the Federal investment in the improvement of the river.

There may be cited numerous indirect, practical benefits from the Ohio River improvement not mentioned by Colonel Hall, which are not susceptible to monetary valuation. The improved Ohio River has recreational features that are widely utilized. The navigation pools afford storage of water for industrial and, in some cases, domestic water supply. Pumping heads have been reduced. During periods of emergency, such as the World War, the water-transportation medium with its reserve capacity was extremely valuable to the country since the rail mediums were congested.

By his assumptions, Colonel Hall has indicated clearly the basis of the economic analysis. Whatever deficiencies obtain are of a minor nature only, and it is believed that they are more than offset by the intangible and indirect benefits.

Colonel Hall discusses the adequacy of the cost of transportation by water as adopted for the determination of the unit savings on the Ohio River. He states that the savings on the two all-important items of coal and steel are based upon line-haul costs of 2 and 3 mills per ton-mile for principal coal movements and about 3 mills per ton-mile for steel movements. An indication of the adequacy of these rates may be had from the following derivation of the cost of transportation for a coal haul, say, from Point Pleasant, W. Va., at the mouth of the Kanawha River, to the mouth of the Miami River below Cincinnati, Ohio.

Annual Cost of Coal-Towing Unit for Operation on the Ohio River (Tow = 10 Standard Barges, Each 26 × 175 × 11 Ft; and the Navigation Season Is a Full Year).—

Cost of Equipment:

Towboat, 1 200 hp, Diesel type	$325 000
Reserve towboat 1 per 10 active, charge	32 500
Barges in transit, 10 @ $14 000	140 000
Barges, 20 additional, at terminals (ratio 2 to 1)	280 000
Total	$777 500

Fixed Charges, Annual:

Interest @ 6% on $777 500	$ 46 650
Plant depreciation (20-yr life)	38 875
Insurance marine, 2½% average life value	9 720
Workmen's compensation insurance (2.28% of payroll)	775
Cargo and liability insurance	18 750
Taxes, 2% average life value	7 775
Total	$122 545

Maintenance and Annual Repairs:

Towboat, 1.1 @ $9 000	$ 9 900
Barges, 30 @ $500	15 000
Total	$ 24 900

Ship Supplies (1.1 Towboats):

Paint, rope, waste, lubricants, etc	$ 4 875
Ice, laundry, linen, etc	1 125
Total	$ 6 000

Payroll (First Watch):	
1 Master, 12 months @ $350	$ 4 200
1 Chief Engineer, 12 months @ $225	2 700
1 Striker Engineer, 12 months @ $125	1 500
1 Watchman, 12 months @ $140	1 680
2 Deck Hands, 12 months @ $110	2 640
Payroll (Second Watch):	
1 Pilot, 12 months @ $275	$ 3 300
1 Mate, 12 months @ $165	1 980
1 Second Engineer, 12 months @ $200	2 400
1 Striker Engineer, 12 months @ $125	1 500
2 Deck Hands, 12 months @ $110	2 640
1 Cook, 12 months @ $140	1 680
2 Chambermaids, 12 months @ $75	1 800
15 Sub-total	$28 020
Relief crews	6 000
Total	$34 020

Subsistence:

15 @ 80 cts per day for 365 days	$ 4 380
Relief crews	780
Total	$ 5 160

Fuel Oil:

1 200 hp @ 0.6 lb per hp-hr = 720 lb per hr,
or approximately 96 gal per hr
Assume 18 hr average use per day and 365 days per season:
96 × 18 × 365 = 630 720 gal per yr
630 720 gal @ 5 cts = $31 535

Summary of Cost:

Payroll	$ 34 020
Subsistence	5 160
Fuel oil	31 535
Maintenance and repairs	24 900
Ship supplies	6 000
Fixed charges	122 545
Payroll, subsistence, and fuel oil cost of reserve boat, 0.1 of $70 715 (arbitrarily added)	7 070
Total annual operating cost	$231 230
Overhead @ 5% (Fleet Superintendent, Assistants, etc.)	11 560
Total annual cost (rounded)	$242 790

Cost of Transportation of Coal on Ohio River from Mouth of Kanawha River to Mouth of Miami River (Tow = 10 Standard Coal Barges; 1 Ton = 2 000 Lb; and No Back-Haul Freight).—

Length of haul, in miles	226
Normal speed, in miles per hour	5
Number of locks in reach of river	12
Size of locks, in feet	110 by 600
Lockages required by tow per lock	1
Lockage time, average for system, hours per lock	0.5
Length of river reach assigned to operation, each lock, in miles	0.5
Loading of tow (down stream only), in tons	8 500
Round-Trip Time, in Hours:	
Assembling and landing time (2 × 2 hr)	4
Lockage time (24 locks at 30 min)	12
Pool time, $\frac{452 - 12}{5}$	88
Sub-total	104
Lost time, all causes, assumed at 35%	36
Total, round trip	140
Navigation season, gross, in hours	8 760
Number of round trips	63
Loading per round trip, in tons	8 500
Commerce per year, in tons	535 500
Haulage per year, in ton-miles	121 023 000
Annual cost, in dollars, per unit tow	242 790
Cost, in mills, per ton-mile	2

The following explanation is pertinent to the derivation of the cost of transportation of coal on the Ohio River as presented in the preceding data. The size of the tow is assumed to be 10 barges. However, the towboat is capable of handling a tow of greater size—up to 16 standard barges—which would require two lockings through each lock. It is assumed that all the traffic proceeds through all the twelve locks on the reach. However, during a considerable part of the year there is sufficient open-river stage to permit the traffic to proceed past the locks through the navigable passes of the dams with the wickets in a lowered position. An exception will be the new Gallipolis Locks and Dam, which will replace Lock and Dam No. 26 below the mouth of the Kanawha River, and Locks and Dams Nos. 24 and 25 above this point, and will require all traffic to proceed through the locks. An assumption of 35% of the normal operation time has been made for lost time to cover delays at locks and lost time due to fog, wind, ice, high water, and all other causes. This is probably conservative for steady coal movements such as obtain for this general reach of the river. It will be noted that no item of profit as such has been included in the derivation. However, the fixed charges include interest at 6% on the initial amount of investment in floating plant. Depreciation is charged on a simple life basis rather than on a sinking-fund basis with compound interest. It is believed that, considering all the aforementioned refining factors in actual practice, a

2-mill rate per ton-mile for coal haul is representative and as such affords an adequate margin of profit for contract-carrier service. Representative costs of transportation by water combined with terminal differentials that are usually in favor of rail haul, afford an equitable basis of comparing the cost of transportation *via* water with the parallel service by rail, from origin to destination.

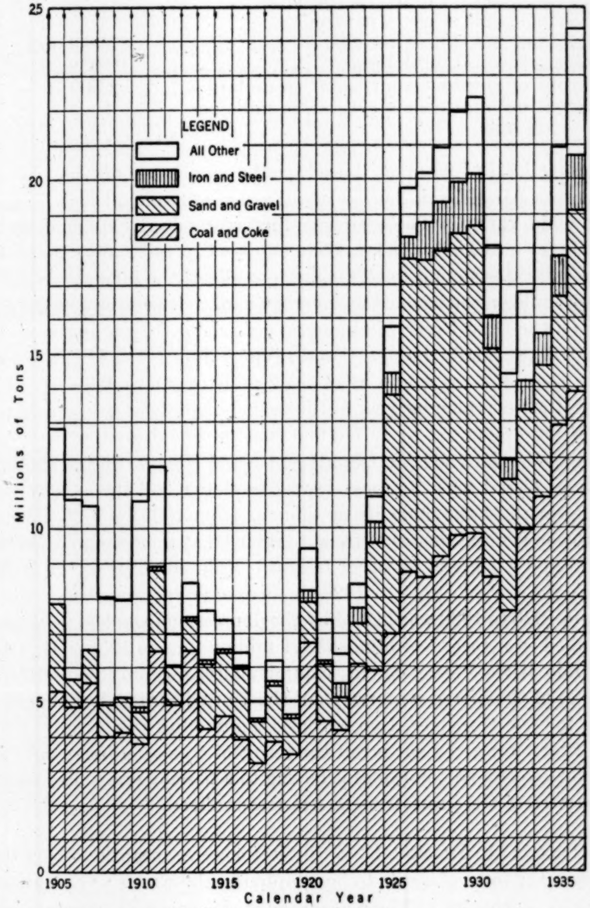

FIG. 5.—OHIO RIVER TONNAGE GRAPH, PITTSBURGH, PA., TO CAIRO, ILL. (1 TON = 2 000 POUNDS)

The profit and loss account for the economic analysis of the Ohio River, as made in the paper, is derived by subtracting the total annual commercial savings from the total annual charges. The following data for the Ohio River obtain for the calendar year 1934 (the latest year of the analysis):

Total freight, in tons	18 636 000
Total freight traffic, in ton-miles	1 783 924 000
Average haul, in miles	96
Savings, net, in mills per ton-mile	6.9
Savings, net, in cents per ton	66.5
Savings, net, total, in dollars	12 359 000
Charges, total, in dollars	10 058 293
Profit on improvement, total, in dollars	2 300 707
Profit on improvement, total, in mills per ton-mile	1.2

An average haul of 96 miles (based on the year 1934) on the Ohio River is equivalent to a parallel rail haul of about equal amount, at least in the upper end of the Ohio Valley. The corresponding average rail rate is about 15 mills per ton-mile for coal haul which takes a commodity rail rate. If the 15% flat increase in rail rates should finally come into effect, the increase would be 2.25 mills per ton-mile on the basis of the average haul. It is improbable that water-haul costs on the Ohio River will increase materially. If an increase of 10% is assumed for water haul, the additional savings due to the full increase, if applicable, in the rail rates would be about 2 mills per ton-mile.

In 1905, the first calendar year of the period of analysis, the freight traffic on the Ohio River amounted to 12 773 000 tons, although at that time only two locks and dams—No. 1 (Davis Island) and No. 6 (Beaver)—and the Louisville and Portland Canal with its lock, were completed and in operation. Fig. 5 shows the growth of the Ohio River tonnage from 1905 to 1936, inclusive, together with the general classes of freight traffic (that is, coal and coke, sand and gravel, iron and steel, and all other freight). The impetus to the growth that occurred in the period, 1924 to 1926, inclusive, is very marked. The steady growth from 1926 to 1930 was halted by the depression from which, however, the traffic climbed to a record of almost 24.4 million tons in 1936. It is apparent that the Ohio River improvement, commercially, not only constitutes an important part of the inland waterways of the United States, but that its field of usefulness for the transportation of basic commodities is steadily increasing. The Ohio River improvement is not the result of a passing fancy on the part of the Federal Government; nor does it belong to a passing era. The vision of the early advocates of the improvement has materialized.

C. L. HALL,[33] M. AM. SOC. C. E. (by letter).—Assumption (1) of the paper was stated in the form of a rule to be adopted in the writer's accounting for the Ohio River improvement. The inaccuracy of this rule was conceded, but it was presented as a condition that tended to become true in time. Professor Grant mentions one situation in which the assumption would not be true in a free economy, and hence it does not tend to become true in time, namely, if the producers favored by the waterway are marginal. As the principal producers of water-borne freight on the Ohio River are the great Pittsburgh steel companies and the Kanawha Valley coal mines, it may be conceded that they are not marginal. Professor Grant also shows that the full difference between rail and water costs cannot be claimed as a benefit if the traffic would not move by rail in the absence of water routes. This statement is correct; but it is moot because, except for a little river sand and gravel, all Ohio River traffic would have to move somehow—even if the waterway were to disappear from the face of the earth—unless the economic level of the region were to fall.

---

[33] Col., Corps of Engrs., U. S. Army, Commanding 1st Engrs., U. S. Army, Fort Du Pont, Delaware.

In preparing the financial summary (Table 5) the writer assumed a balance at the end of 1904—with everything paid for at that time. In General Kutz's official unpublished report[34] he states that there is no doubt that the savings effected by the Ohio River during the period 1875–1904 greatly exceeded the expenditures. However, this assumption, although it may be entirely justified, gave an unduly rosy picture of the situation from 1905 to 1910. Incidentally, the cost of Ohio River improvement prior to 1905 is such a small share of the total expenditures that research into commerce before that date is unjustified. It may be added that comparisons of benefits prior to 1905 are of very slight value. The Chesapeake and Ohio Railroad, for instance, was not built until 1905. Before that time, therefore, the river was the normal method of carrying freight between river towns, and there is no base upon which comparisons of costs with competing carriers could be computed adequately.

The main point discussed by Professor Grant raises a question that extends far beyond the Ohio River. He declares that public works are socially unprofitable unless they give at least as great a return as the private investments displaced by the diversion of taxpayers' funds. In its literal form the principle is impossible of application because it would rule out, completely, structures like the Lincoln Memorial. What the statement would mean in practice is that public works competing with privately owned facilities should not be constructed unless they could produce revenues far greater than those accounted for by non-competing public works; that is, a lock and dam must show much greater benefits than a new post office. Professor Grant's complaint that profits during the period of regulation are not a proper charge against losses after canalization was begun, has a certain measure of justification. He establishes his case quite neatly in Table 7. However, the fact that there were profits for 1930–1933, when most other activities in the United States were losing money, is itself proof of a rather wise investment.

The writer must dissent from the view that the life of a prospective public investment should be calculated in commercial terms. Experimental commercial investments are only justified by large prospective profits. The Government, however, can afford to experiment (or pioneer) on a public project with an undoubtedly long engineering life, subject to the hazards of a shorter economic life. If the Government refuses to do this kind of experimenting, nobody will. Will the country be better off if such pioneering enterprises are never undertaken?

Mr. Lavis' distinction between internal and external waterways also could not be applied in practice. If it were made absolutely rigid the enormous public benefits caused by the improvement of the St. Mary's River, for instance, would never have been accomplished. If the distinction were not made absolutely rigid, it would assuredly be disowned by any American Government within the range of practical politics. Moreover, even on Mr. Lavis' principle, the secondary local benefits from channels to the ocean, obtained on streams such as the Upper Hudson River, would cause a subsidy to certain types of internal waterway traffic.

---

[34] Rept. of June 30, 1926.

The writer does not believe that he has overlooked the advantages in distance of the usually shorter land route. In the preparation of Table 4 the comparison was between terminals, and the benefits were developed on a basis of ton-miles measured by water. The writer hoped that Table 6 would have made that point entirely clear.

In Mr. Lavis' discussion, as in some others, there seems to be a feeling that the costs given in the paper are based on distances between main-line termini. This is not true. The comparison was for rail rates between producer and consumer on the one hand, and net costs plus profit to the competing shipper (rail rates, water costs, and terminal charges) on the other. These values were reduced to ton-miles measured by water in order to give a unit by which typical studies could be applied generally; but the very methods used gave the all-rail carrier complete credit for his shorter mileage.

Mr. Barrett's opinion that there is no difference, in final result, between benefits derived by producers and those derived by a necessarily limited number of consumers has considerable logic behind it. It seems probable, however, that public funds will not be provided for waterway improvement unless it can be shown clearly that a direct financial saving is obtained by a large number of consumers. Of course, the benefits from a public route of transportation cannot be distributed uniformly over the entire nation; but they must be open to all the people of the region affected, and not merely to stockholders of great corporations.

The remarks of Colonel Daley and Mr. Byrns are much appreciated. The writer did not cover the general regional benefits that have accrued to upper river ports from the Ohio River improvement, because he could find no method of making a statistical comparison. The point that real new wealth has been produced by Ohio River development, however, is a vital one, and should have been discussed.

Messrs. Willoughby and Faucette attack the improvement of the Ohio River on two general grounds, as follows: (1) That the improvement, in so far as it does permit cheaper shipment, merely diverts money from rail carriers to water carriers; and (2) that if the Federal costs were charged against the shipper there would be no cheaper shipment. If the net total of goods moved in the United States were constant (that is, if the country were static), the first complaint would probably be valid. Along that line, every new ocean vessel (except a replacement for a scrapped one) would reduce the revenues of existing ocean carriers. The nation has always refused to make any such melancholy admission, however. It has always claimed that the reduction of distances in money or time caused by technical improvements in means of transit has increased total consumption, and total freight moved, by a far larger amount than the losses caused to pre-existing cargo carriers. Beyond dispute this was the effect of the substitution of railroads for mule-drawn wagons in the Middle West seventy years ago.

If true waterway costs are greater than rail costs, Messrs. Willoughby and Faucette are correct in their second complaint. The aim of the writer was to show that the costs of shipment by the Ohio River were, on the whole, less than those by competing carriers. His proof was based on certain carefully stated assumptions, followed by an investigation of all the data that he could procure. The assumptions are those used in the study of proposed waterways for many years. Perhaps more valid ones could be prepared, which would be concurred in by those responsible for authorizing public expenditures; but the writer ventures to doubt it. The only assumption criticized constructively is the fifth, in which the writer excluded, for accounting purposes, any allowance for unpaid taxes. The question of charging unpaid taxes as a constructive expense of Government enterprises is a very difficult one. If full interest and depreciation are charged, and if the Government "polices" the work with maintenance funds, it is difficult to show that taxes are an equitable charge against the property. On the other hand, there is a certain degree of statistical error in comparing tax-free carriers with taxed ones. Every one should welcome a rule to correct the rather unsatisfactory state in which the present situation leaves the student of governmental enterprises.

The discussers are wrong in believing that the Ohio River pools are not beneficial to sand-diggers. Sand is also more readily carried in pools of fixed minimum depth. From his experience as a District Engineer, the writer can assure them that the improvement does not prevent the formation of new bars.

Allowance has already been made for greater circuity of water routes. In the preparation of Table 4, as stated in replying to Mr. Lavis, the basic comparisons were between movements from origin to destination by different routes. No question of relative lengths of haul entered into this matter until a final benefit per ton per route was determined. This benefit was then distributed as commercial benefit per ton-mile measured by water, so that all rail advantage of shorter haul was already credited; for example, in the movement of steel pipe from Youngstown, Ohio, to Memphis, Tenn., the shipper's cost is:

By rail (tariff charges)		$14.60
By water:		
Rail rate to river terminal	$0.335	
Line cost of river movement; 1 188 miles at 3 mills per ton-mile	3.56	
Terminal charges	0.75	
Total water cost		$4.645
Commercial benefit		$9.955
Unit ton-mile commercial saving		$0.0084

It will be noted that this commercial saving, although calculated in mills per ton-mile measured by water as the only convenient method of generalization, gives the railroad full credit for its shorter haul.

As to the criticism of Table 6, the journey from Cincinnati, Ohio, to Louisville, Ky., was selected because these two river cities are separated by a distance of about the length of the average haul (119 miles). The object of the table was to check Table 4 by an independent calculation. The writer was astonished at his own results. Incidentally, the rail and water distances from Cincinnati to Louisville are about identical. It is believed that the criticism of this comparison between rail and water methods of moving a typical ton a typical mile would have been more useful if data had been given for making the same comparison over some other trip between major river ports.

Colonel Covell's very interesting discussion presents a highly valuable cost analysis of steamboat transportation. He shows that the values derived from confidential reports by the big river operators are inherently reasonable, and he thus supports the general accuracy of the statement of savings (see Table 4). The writer has made no claim that the improvement is justified, wholly or in part, by its regulatory effect on rail rates. Probably it is true, as Colonel Covell states, that the existence of the improvement has inhibited a general increase in coal rates; but it is believed that internal improvements constitute a rather expensive means of rate regulation. In that respect, the writer tends to agree with Messrs. Willoughby and Faucette.

During the progress of this discussion the commercial data for the calendar year 1937 have become available. They give a total commerce of 23 356 676 tons, an increase of 25% over 1934; and of 2 671 926 225 ton-miles, an increase of 50% over 1934. The average haul for 1937 was 114.39 miles.

Undoubtedly, the discussions have clarified the points upon which differences as to matters of principle are held. There is no certainty as to what profits to the public should be required from public works competing with privately owned ones. There is no certainty as to whether taxes not paid by the Government should nevertheless be arbitrarily added to public costs for purposes of comparing accounts. There is no certainty as to the minimum distribution of private advantages, secured from public works, required to establish such advantages as public benefits. These questions, of course, are political in their nature; but the political decision should follow a crystallization of engineering opinion. Needless to say the final decision should apply to all public works competing with commercial investments. It was the writer's aim to use this paper on the Ohio River as a case study of a completed competing project, which would bring out all disputes on principle, besides contributing to technical literature pertaining to the Ohio River. His aim seems to have been accomplished—at least in part.

SOLUTION OF TRANSMISSION PROBLEMS OF A WATER SYSTEM

By Ellwood H. Aldrich,[1] M. Am. Soc. C. E.

With Discussion by Messrs. Lynn Perry, Charles M. Mower, Jr., Thomas R. Camp, Harold E. Babbitt, C. Maxwell Stanley, Warren E. Wilson, Harold K. Palmer, F. Knapp, Weston Gavett, and Ellwood H. Aldrich

Synopsis

Some of the problems commonly experienced in the design of the transmission and distribution elements of a water system are solved in this paper which presents a rational method involving an expansion of the graphical solution[2] first suggested by the late John R. Freeman, Past-President and Hon. M. Am. Soc. C. E. A brief summary is given of the many variable and, from a practical standpoint, sometimes indeterminate, factors that must be considered in assembling the data upon which the design must be based. General cases are presented giving the solution of the more common problems encountered in design, with an illustration of the use of several of these general cases in the solution of a typical design problem.

Introduction

The design of the transmission and distribution facilities of a water system presents a complex and absorbing problem for one engaged in such a task. A mathematically accurate determination of the results to be expected in designing intricate grid systems or important reinforcements is impossible of attainment from a practical standpoint. When it is realized, however, that these elements of a water system commonly exceed 50% of the total value of such a system and that they materially influence the cost, as well as the adequacy of service, the reason becomes apparent why all the knowledge that is available should be utilized to secure an efficient design.

The opportunity to design a complete water transmission and distribution system of any magnitude is not often presented to an engineer. His work is usually concerned with providing extensions and reinforcements to existing

---

Note.—Published in October, 1937, *Proceedings*.

[1] Associated with Reeves Newsom, Cons. Engr., New York, N. Y.

[2] *Journal*, New England Water Works Assoc., Vol. 7 (1892), p. 49.

systems. It is of primary importance for him, therefore, to determine the operating functions of the existing system as the basis for a determination of the necessity for, and the extent of, the most effective reinforcements.

Basic Data

Satisfactory service requires that a sufficient quantity of water shall be furnished to all parts of the system at pressures adequate for the requirements of the consumers under all conditions of their demands. To create such service proper reserves must be available in the form of pumping, transmission, and distribution capacity, often supplemented by storage, to meet all reasonable contingencies.

The more important basic data required by the designer before undertaking the solution of the hydraulics of a problem are: (*a*) The pressure and flow requirements under the varying rates to be expected in the respective parts of the system; (*b*) the topography of the service areas; (*c*) the pumping arrangements and pump characteristics in other than gravity systems; (*d*) the location, quantity, and elevation of storage; and (*e*) the condition of the pipe system in so far as the carrying capacities of its many elements are concerned.

Williams-Hazen Formula.—Many formulas have been developed to present the results of the flow of water in pipes. The Williams-Hazen formula has become more generally used than any other for water-works conditions because of the ease of its application with the aid of tables,[3] or by the use of a special slide-rule. It gives acceptable results provided the coefficient is carefully determined. This formula is:

$$V = C\,R^{0.63}\,S^{0.54}\,0.001^{-0.04} \qquad (1)$$

in which V = velocity of flow, in feet per second; C = coefficient, dependent on the interior conditions of the pipe (sometimes called the coefficient of roughness); R = the hydraulic radius or the area of the pipe divided by the wetted perimeter, in feet; and, $S = \frac{H}{L}$, the slope of the hydraulic gradient or the head loss, in feet per thousand feet. In a closed pipe of constant diameter, with flow under pressure, $R^{0.63}$ becomes a constant, so that,

$$V = C\,K\,S^{0.54} \qquad (2)$$

In other words the velocity, and, therefore, the quantity flowing in a given size of pipe, varies directly as the coefficient, C, and as the 0.54 power of the hydraulic gradient.

Therefore, several fundamental relations result: With C constant, V varies as $S^{0.54}$, or S varies as $V^{1/0.54}$; with V constant, S varies as $C^{1/0.54}$, or C varies as $S^{0.54}$; and, with S constant, V varies directly as C.

In using the flow tables based upon this formula, which were compiled by the late Gardner S. Williams and Allen Hazen, Members, Am. Soc. C. E.,[3] it is necessary to have some convenient means of interpolating between the standard flows, sizes of pipe, losses of head, and coefficients set forth therein. By plotting the standard flows as determined from the Williams-Hazen tables, or by slide-rule, on logarithmic scale, and, similarly, by plotting S against $S^{0.54}$ and $S^{1/0.54}$, as shown in Fig. 1, the interpolation and conversion of the varying factors of the formula are facilitated. With this formula as a base, it is possible to make all computations by the use of Fig. 1.

---

[3] "Hydraulic Tables," by the late Gardner S. Williams and Allen Hazen, Members, Am. Soc. C. E., John Wiley & Sons.

SOLUTION OF GENERAL PROBLEMS

General.—Specific problems usually involve as a first step the simplification of intricate arrangements of many pipe lines and their combination into one or more equivalent lines. In making these combinations, several general cases arise in almost every problem. These will be illustrated by the following general cases: (I) Pipe connected in series; (II) pipe connected in parallel and in series; (III) "take-outs" and "put-ins"; (IV) compound storage; (V) pipe connected in parallel with intermediate cross-connections; and, (VI) pipe connected in grids.

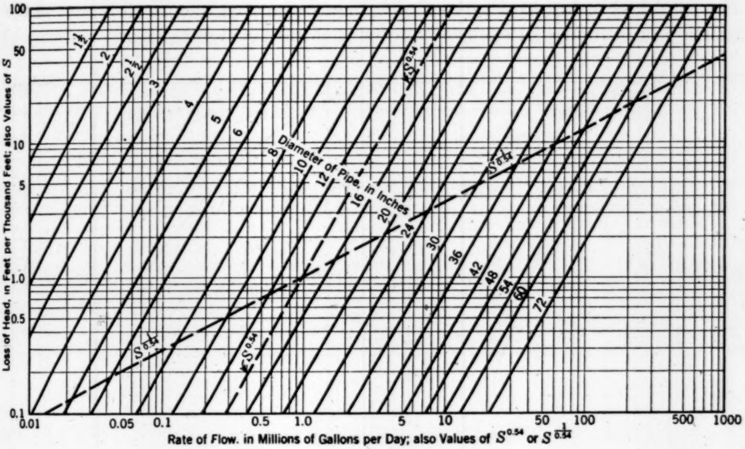

FIG. 1.—FRICTION LOSS BY EQUATION (1)

It is not the intent to imply that a graphical solution of the simpler combinations must be resorted to; neither is it always possible or necessary to take the time, or to make the effort, to achieve an accurate combination of many complex lines. Most combinations can be made by slide-rule computations without graphical help, but in certain cases much better progress can be made by using a graphical solution than is possible by trial and error, or by mathematical methods, and familiarity with the graphical representations of the simpler combinations is a prerequisite to an easy solution of the more complex systems.

The term, "hydraulic grade," is used in this paper to denote the piezometric pressure in the pipe or conduit at the point in question. Although in most of the cases discussed herein the coefficient has been assumed as 100, in order to permit the use of Fig. 1 without further computation, the special slide-rule permits solutions using actual coefficients with equal ease. It is also apparent that the graphical method described herein is applicable to other formulas expressing the results of flow of water in pipes.

Case I.—Pipe Connected in Series.—Fig. 2 is a graphical representation of the loss of head under varying rates of flow through a pipe line consisting of several pipes of different diameter connected in series. In such a line the total head loss for a given flow is a summation of the loss of head in each section for that flow. With abscissas representing the rate of flow and ordinates the loss of head under those rates of flow, curves are constructed for each section of pipe. The total loss of head for several pipe lines connected in series consists of the addition of ordinates of each section for each rate of flow.

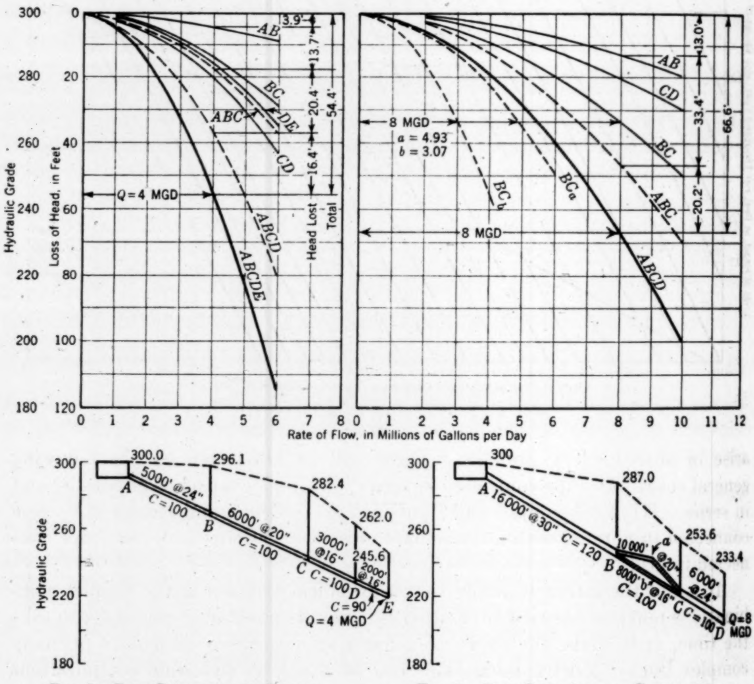

FIG. 2.—PIPE CONNECTED IN SERIES; CASE I

FIG. 3.—PIPE CONNECTED IN SERIES AND PARALLEL; CASE II

Case II.—Pipe Connected in Parallel and in Series.—Fig. 3 is a graphical representation of the loss of head under varying rates of flow through three sections of pipe, one of the sections consisting of two pipes connected in parallel. The graphical combination of pipe connected in parallel is effected by adding the abscissas of each pipe at each loss of head, since the loss of head through a given section consisting of several pipes connected in parallel is the same in each pipe and the total flow in the section is the sum of the flows in each pipe. Having determined the equivalent pipe curve for the section of pipes connected in parallel, the three sections of pipe connected in series are combined as illustrated in Case I.

Cases I and II are simple combinations of pipe easily solved with the aid of the hydraulic slide-rule. However, the graphical combination of such pipe arrangements greatly facilitates solutions in more complex combinations, involving consumption at points along the line, the introduction of water from storage or from other sources, and those combinations of pipe for which several factors are dependent upon each other.

The graphical solution of these more complex systems requires the moving of the quantity-head loss curves to represent the effect of variation in elevation of storage, the putting in or taking out of quantities of water, and the flow and pressure characteristics of centrifugal pumps. These solutions are facilitated by a graphical representation of the quantity-head loss relation which can be moved easily to represent the variations in conditions. Convenient transparent media for such graphs are prepared in the form of small rectangles about 4 in. by 6 in. in size, cut from thin celluloid, processed or coated on one side to aid the drawing of the quantity-head loss curves and their removal when no longer required. Careful trimming of the edges aids accurate placing in the proper position. They are sufficiently rigid to lie flat and stay in place, and their transparency renders possible the use of several cards superimposed one upon another.

Case III.—"Take-Outs" and "Put-Ins."—Fig. 4(*a*) is a graphical representation showing the taking out or putting in of a certain quantity of water from, or into, one of two mains connected in parallel. The quantity-head loss curve, *A E C*, representing the flow in Main *A E C*, is drawn upon the right of the *Y*-axis as shown. With no "take-out" or "put-in" at Point *B*, Curves *A B* and *B C*, representing the flow conditions in Mains *A B* and *B C*, are drawn upon the left of the *Y*-axis and combined as in any two pipes connected in series, as illustrated in Case I. A rate of flow of 8 mgd at Point *C* results in a loss of head of 59.8 ft, 4.3 mgd flowing through Main *A B C* and 3.7 mgd through Main *A E C*.

With a "take-out" at the rate of 4 mgd at Point *B*, Curve *A B* is moved to the right a distance equivalent to 4 mgd on the *X*-axis, as shown in Curve *A B''*, before combination with Curve *B C* to form the curve, $A\ B\ C^T$. In extending Curve $A\ B\ C^T$ to the right of the *Y*-axis, flow in Pipe *B C* reverses in direction, causing Curve *B C* to assume the position, *B C'*, which is used in combining the two curves for flows in Mains *A B* and *B C*. With a flow from Point *C* at the rate of 8 mgd and a "take-out" of 4 mgd at Point *B*, the loss of head from Points *A* to *C* is 84.5 ft, 4.5 mgd flowing through Main *A E C*, 7.5 mgd through Main *A B*, and 3.5 mgd through Main *B C*. By following vertically up from the intersection of this quantity with Curve $A\ B\ C^T$ to the intersection with Curve *A B''* the loss of head in Main *A B* is found to be 58.5 ft.

The intersection of Curve $A\ B\ C^T$ with the *Y*-axis gives the loss of head in the system at which reversal of flow in the main, *B C*, occurs. With any flow at Point *C* less than is given for this loss of head, the flow through Main *A E C* exceeds the quantity taken out at Point *C* and the remainder flows toward Point *B* to satisfy the "take-out" there. In other words, the scaled rate of flow between Curves $A\ B\ C^T$ and *A E C* represents the draft at Point *C*; that between $A\ B\ C^T$ and the *Y*-axis represents the flow back from Point *C* to Point *B* and the total flow through Main *A E C* is the sum of the two, or the scaled distance from Curve *A E C* to the *Y*-axis. The ordinate of the intersection of Curves $A\ B\ C^T$ and *A E C* measures the loss of head from Points *A* to *C*, 6.5 ft, at which there can be no flow out of Point *C* if the "take-out" of 4 mgd at Point *B* is satisfied.

If 4 mgd is assumed to be put into the system at Point *B*, Curve *A B* must be moved to the left of the *Y*-axis, opposite to its position for a "take-out", as Curve *A B′*, before combining with Curve *B C* to form Curve $A\ B\ C^P$. With an 8-mgd rate of flow at Point *C* and a "put-in" of 4 mgd at Point *B*, the loss from Points *A* to *C* is 47.3 ft, causing a flow through Main *A E C* of 3.3 mgd, through Main *A B* of 0.7 mgd, and through Main *B C* of 4.7 mgd. Following vertically up from the intersection of this total rate of flow with Curve $A\ B\ C^P$ to Curve *A B′*, the loss of head in Main *A B* is 1.2 ft and, similarly, in Main *B C* the loss is 46.1 ft. From these curves, the quantity-head loss relations in all pipes are established for flows at Point *C* under the three conditions assumed at Point *B*, namely, no "take-out" or "put-in", a "take-out" of 4 mgd, and a "put-in" of 4 mgd.

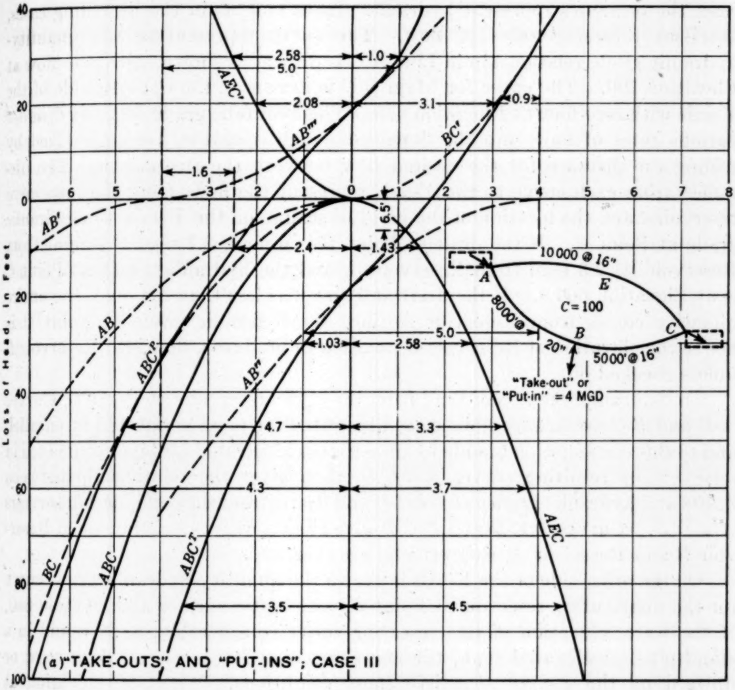
Another use of the curves in Fig. 4(*a*) can be made for reservoirs at Points *A* and *C*, capable of putting out or taking in the quantities of water required to balance the system without appreciable changes in elevations. A "take-out" of 4 mgd at Point *B*, when the elevation of Reservoir *C* is 30 ft below Reservoir *A*, causes a flow at the rate of 5 mgd from Points *A* to *B*, 1 mgd from Points *B* to *C*, and 2.58 mgd through Main *A E C*, or a total of 7.58 mgd flowing out of Reservoir *A* and 3.58 mgd flowing into Reservoir *C*. The hydraulic grade at Reservoir *C*, of course, is 30 ft below that at Reservoir *A*, and at Point *B* it is 27.5 ft below that at Point *A*, and 2.5 ft above that at Point *C*.

If Reservoir *C* is 20 ft above Reservoir *A*, under a similar "take-out" at Point *B*, there is a flow from Point *C* to Point *A* through Main *A E C* of 2.08 mgd, a flow of 3.1 mgd from Points *C* to *B*, and one of 0.9 mgd from Points *A* to *B*, or a total flow of 5.18 mgd leaving Reservoir *C* and of 1.18 mgd entering Reservoir *A*. The hydraulic grades are determined similarly as described.

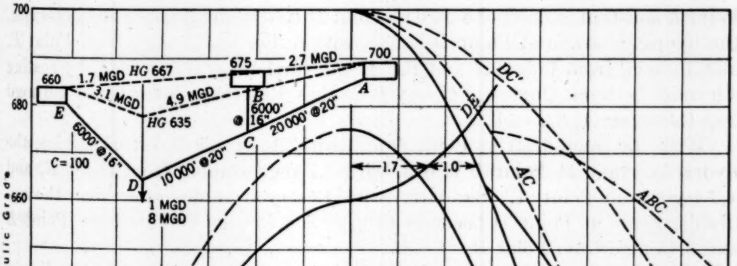
With a 4-mgd "put-in" at Point *B* and the elevation of Reservoir *C* 10 ft below Reservoir *A*, a flow of 1.43 mgd is caused from Point *A* to Point *C* in Main *A E C*, 1.6 mgd from Point *B* to Point *A*, and 2.4 mgd from Point *B* to Point *C*, or 3.83 mgd flowing into Reservoir *C* and 0.17 mgd into Reservoir *A*.

With a similar "put-in" at Point *B*, and Reservoir *C* 30 ft above Reservoir *A*, the resulting flow from Point *C* to Point *A* in Main *A E C* is 2.58 mgd, from Points *B* to *A*, 5 mgd, and from Points *C* to *B*, 1 mgd, or 7.58 mgd flowing into Reservoir *A* and 3.58 mgd flowing out of Reservoir *C*.

Case IV.—Compound Storage.—Fig. 4(*b*) is a graphical solution of the losses of head under varying rates of flow from a system of supply or distributing reservoirs. With three reservoirs as shown, two of the reservoirs and their transmission mains are first combined into one source. Points *A* and *B* represent two supply reservoirs or intakes not subject to appreciable variations in levels, one situated at Elevation 700, and the other at Elevation 675. In this



(a) "TAKE-OUTS" AND "PUT-INS"; CASE III



(b) COMPOUND STORAGE; CASE IV

FIG. 4

case, the ordinates represent hydraulic grades and, as in the preceding cases, abscissas represent rates of flow. The curve representing the quantity-hydraulic grade relationship in Line *A C* is drawn, as shown, with zero flow at Elevation 700. The curve for Main *B C* is drawn on the opposite side of the *Y*-axis with zero flow at Elevation 675. The hydraulic grade at Point *C* under various rates of flow, and the flows from each reservoir, are determined by scaling the distance for the desired flow between the two curves. The distances from each curve to the *Y*-axis represent the flows from the respective reservoirs, and the location of the point of scaling on the *Y*-axis, the hydraulic grade at Point *C*. If the draft at Point *C* is 6 mgd, 3.7 mgd is coming from Reservoir *A*, 2.3 mgd from Reservoir *B*, and the hydraulic grade at Point *C* is at Elevation 660.5. If the draft at Point *C* is less than 2.9 mgd, the entire quantity comes from Reservoir *A* since the hydraulic grade at Point *C* is above the elevation of Reservoir *B*, tending to produce a flow into Reservoir *B* unless checked off.

To determine the loss of head from these two reservoirs at Point *D*, Curves *A B* and *B C* are first combined, as illustrated for pipes connected in parallel, and to this combination is added Curve *C D* as illustrated for pipes connected in series. The resulting curve, *A B C D*, then gives the relationship between drafts and hydraulic grades at Point *D* and drafts from the combined Reservoirs *A* and *B*. Curves *A C D* and *B C D* give the conditions existing when Reservoir *B* and Reservoir *A*, respectively, are shut off.

On the other side of the *Y*-axis is drawn the quantity-hydraulic grade curve for the distribution reservoir at Point *E*, with water surface at Elevation 660. If the water elevation of this reservoir varies considerably, as it would in a stand-pipe, or elevated tank, the curve for Line *DE* is moved downward or upward on the *Y*-axis to satisfy these conditions. With the elevation at Point *E* constant, a draft of 8 mgd at Point *D*, and with all reservoirs in service, the hydraulic grade at Point *D* is 635, with a flow of 3.1 mgd from Point *E*, and 4.9 mgd from Points *A* and *B*. It can further be determined, by scaling 4.9 units between Curves *A C* and *B C*, that Reservoir *B* furnishes 1.6 mgd and Reservoir *A*, 3.3 mgd.

With the same draft at Point *D* and with Reservoir *B* out of service, the hydraulic grade at Point *D* is 623, with 3.7 mgd coming from Point *E*, and 4.3 mgd from Point *A*. Similarly, with Reservoir *A* out of service, the hydraulic grade at Point *D* becomes 616, with 4.15 mgd coming from Point *E* and 3.85 mgd from Point *B*.

Assuming that the draft at Point *D* is only 1 mgd with both supplies in service, the hydraulic grade at this point is above that at Point *E*, and there is a flow to the distribution reservoir. In such a case the flow from Point *A* and Point *B* is 2.7 mgd, but 1.7 mgd goes to Point *E*, 1 mgd is taken off at Point *D*, and the hydraulic grade at Point *D* is 667. As shown in Fig. 4(*b*) the curve for Main *D E* is reversed about the *Y*-axis for elevations above 660.

It is often necessary to determine the effect of a sustained but variable draft of a maximum day upon a distribution reservoir such as that at Point *E*. This is capable of determination from the curves. By setting up the hourly rates, a table can be compiled giving the drafts from or to each reservoir and the hydraulic grades at the desired points. This can be further complicated when the storage in any of the reservoirs varies in elevation by any appreciable extent.

A study such as this is particularly important in determining the size and elevation of storage. A sufficiently accurate determination can be made upon an hourly basis by converting the quantity drawn from a stand-pipe or tank to gallons, and from the diameter of the tank, converting this to drop in water elevation, in feet. During the next hour the curve must be moved down by the quantity of the drop. This will result in less water being drawn from the tank or the stand-pipe. This approximation can be continued, hour by hour, until, the peak loads past, or the lowering level in the tank (or more generally a combination of the two), the hydraulic grades produce a flow toward the tank and it begins to fill. In this manner curves can be drawn for almost any condition, giving the draft and hydraulic grade at a certain point, the flow from or to a stand-pipe or tank, the flows from the sources of supply, and the hydraulic grade, or its equivalent, the elevation of water in the tank.

Case V.—Pipes Connected in Parallel with Intermediate Cross-Connections.—Fig. 5(*a*) represents the flow conditions and losses of head through two pipes connected in parallel with an intermediate cross-connection (see Fig. 5(*b*)). The arrangement of the pipes and the construction of the individual quantity-head loss curves are self-explanatory. In all examples involving cross-connected pipe, the cross-connection is in effect a "take-out" of one pipe and a "put-in" to another of an unknown quantity, dependent upon the carrying capacities of the several pipes.

Since the hydraulic grades at the junction of Pipes (1) and (2) are the same, curves for these pipes are drawn, as shown, on each side of the Y-axis. It is unnecessary to have a definite flow through the system in order to convert it into an equivalent pipe; therefore, in Pipe (2) a loss of head of 30 ft is assumed. This produces a flow of 4.22 mgd through Pipe (2). The remaining unknowns are h_1, h_3, h_4, h_5, Q_1, Q_3, Q_4, and Q_5. It is known, however, that at all junction points the hydraulic grades are the same in each pipe, and the quantity flowing to and from each junction is in balance. Usually, by inspection, it is possible to determine the direction of flow in interior pipes, and curves for these pipes can be laid off, either to the right or to the left, with zero flow at the assumed head loss to the junction in question. In this case, from the lengths and sizes of pipe, it is evident that flow in Pipe (3) is from Point C to Point B, that a part of the flow in Pipe (2) is taken out at the cross-connection, leaving a smaller quantity to flow through Pipe (4). This "take-out" becomes a "put-in" at the other end of the cross-connection and is added to the flow in Pipe (1) to produce the flow in Pipe (5).

Curves (4) and (5) are traced on a movable card from Curves (4)′ and (5)′, which are set up anywhere. It is known that the losses of head to the ends of Pipes (4) and (5) are the same; therefore, they are drawn together as shown in Fig. 5(*a*). From inspection, it is seen that Curve (4) must intersect Curve (2) at Point *a*, at the same loss of head as the beginning of Curve (3). Similarly, Curve (5) must intersect Curve (1) at Point *b*. The card on which Curves (4) and (5) are drawn must be adjusted, therefore, so that Curve (4) intersects

Curve (2) at Point *a*, Curve (5) intersects Curve (1) at Point *b*, and the *Y*-axis of Curves (4) and (5) must intersect Curve (3) at a point, *c*, with the same loss of head and, therefore, in the same horizontal plane in Fig. 5(*a*), as Point *b*. Having adjusted the card in this manner, the following conditions have been met:

$$H = h_1 + h_5 = h_2 + h_4 = h_2 + h_3 + h_5 = h_1 - h_3 + h_4 \ldots\ldots \quad (3)$$

or, in feet, 72.8 = 32.4 + 40.4 = 30.0 + 42.8 = 30.0 + 2.4 + 40.4 = 32.4 − 2.4 + 42.8; and,

$$Q = Q_1 + Q_2 = Q_4 + Q_5 = Q_2 - Q_3 + Q_5 = Q_1 + Q_3 + Q_4 \ldots\ldots \quad (4)$$

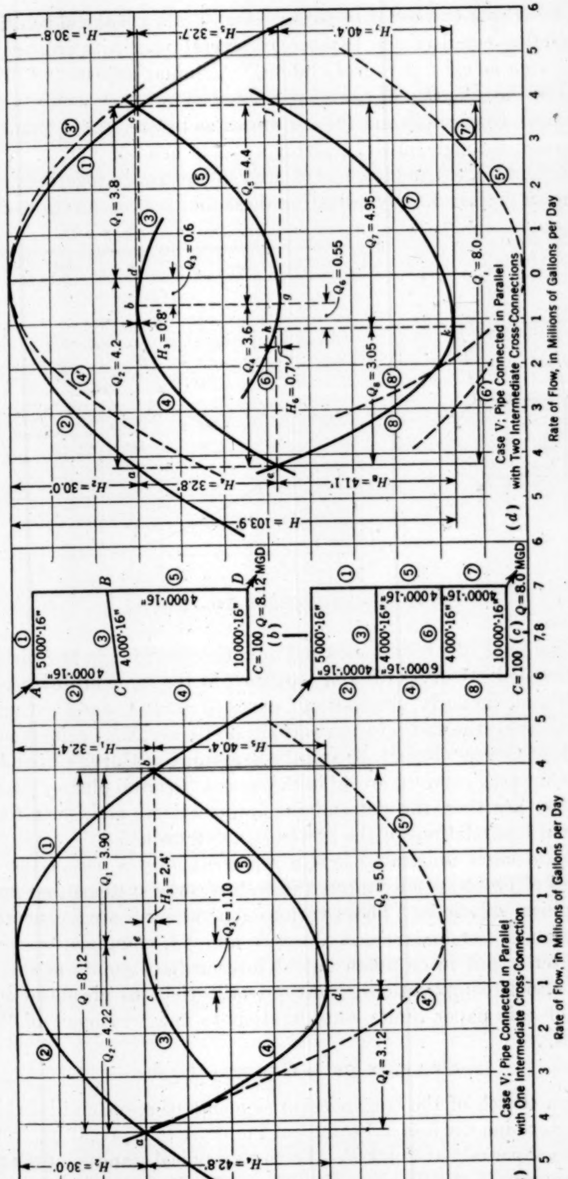
or, in million gallons daily, 8.12 = 3.9 + 4.22 = 3.12 + 5.0 = 4.22 − 1.1 + 5.0 = 3.9 + 1.1 + 3.12.

In Fig. 5(*b*) is shown a further step of the preceding problem with an additional interior connecting pipe. Similar procedure is adopted for its solution. Curves (1) and (2) are drawn as before and a loss of head of 30 ft is assumed in Pipe (2) giving a flow of 4.2 mgd. Since Pipes (3) and (4) begin at the same hydraulic grade, Pipes (5) and (6) and Pipes (7) and (8) end at the same grade, these sets of curves are drawn together, and there are three cards to be adjusted.

Curves (3) and (4) must start with the loss of head that occurs in Pipe (2), which, by assumption, is 30 ft. Similarly, from the condition of a balanced hydraulic grade at each junction, Curves (3) and (4), (5) and (6), and (7) and (8) must be adjusted so that the respective intersections, Points *a* to *k*, are as shown. Curve (3) can be drawn the same as in the previous example, but here it is as convenient to combine it with Curve (4) on the same movable card. There are many ways to arrange the curves for quantity-head loss. In these illustrations curves concave downward indicate flow away from the inlet, and curves concave upward indicate flow toward the outlet or flows from, or to, the apices of the curves. The interior curves may be considered either way as long as the fundamental relationships hold.

In these examples, the loss of head must be the same by any route connecting two points; and the quantity flowing through any straight section cut entirely through the system, must be the same, due regard being given to the direction of flow. The total head loss in the last system of pipes is 103.9 ft for a flow of 8 mgd. An equivalent pipe would be computed as follows: $\frac{103.9}{24.3}$ = 4 280 ft of 16-in. pipe, $C = 100$.

In the last illustration it is interesting to determine how much the cross-connecting pipes reduce the total loss of head. With two 16-in. pipes connected in parallel, one 20 000 ft, and the other 13 000 ft, long, eliminating the cross-connecting pipes, the equivalent pipe is 4 400 ft of 16-in. pipe, $C = 100$. The head loss is 24.3 × 4.4 = 106.9 ft, or the saving in head is only 3 ft. The conclusion is that pipes connecting points of approximately equal pressure are of little value in reducing the friction loss. As these pipes approach a parallel connection with the main pipes or connect points of greater pressure difference, their value in reducing losses or increasing flows becomes greater.



(a) Case V: Pipe Connected in Parallel with One Intermediate Cross-Connection

(d) Case V: Pipe Connected in Parallel with Two Intermediate Cross-Connections

FIG. 5

Case VI.—Pipes Connected in Grids.—Fig. 6 is a graphical solution of the pressure and flow conditions in a system of several pipes with cross-connections both ways, such as exist in a grid system. A similar adjustment of curves is required as in Case V, Fig. 5.

In this case, Curves (1) and (2) are drawn as before, and a quantity of 7.5 mgd is assumed through Line (2), giving a loss of head of 36.6 ft. Curves (3) and (10), (4) and (5), (6) and (9), and (7) and (8) are drawn together on movable cards as shown in Fig. 6. By adjusting these four sets of curves to obtain the proper intersections, the head losses and quantities flowing in the various pipes can be determined. Curves (3) and (10) start at the same ordinate as the end of Curve (2) and, similarly, the ends of Curves (3) and (4) and the beginning of Curves (6) and (9); the ends of Curves (9) and (10) and the beginning of Curve (8); the ends of Curves (5) and (6) and the beginning of Curve (7); and, finally, the ends of Curves (7) and (8) are all in the same horizontal planes, respectively. Points *a* to *m* are then the determining intersections, and, once found, the quantity-head loss relations of the system are determined.

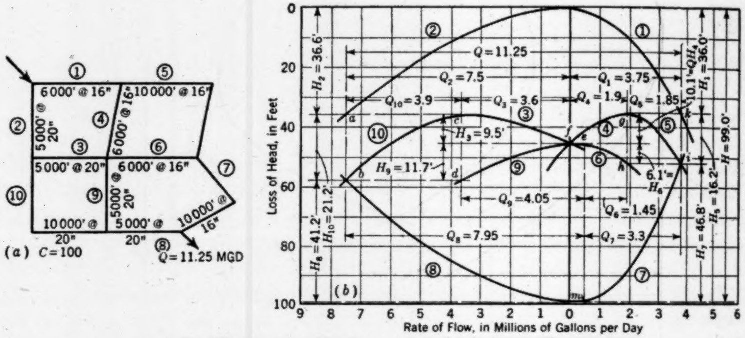


FIG. 6.—PIPE CONNECTED IN GRID, CASE VI

The general cases illustrated herein represent only a few of the simplest combinations of problems encountered in water-works systems that are adaptable to graphical solutions. These various general cases are frequently found in combinations. For instance, in Cases V and VI, complications are introduced if water is put in or taken out at intermediate points in the systems illustrated. Such complications, however, still yield to graphical solutions. The scope of this paper limits consideration to the treatment of the more general cases.

SOLUTION OF A GENERAL CASE

Fig. 7 is a sketch of the transmission elements of a system[4] in which it is desired to determine the loss of head from Points *A* to *X*, resulting from a fire flow of 1 500 gal per min at Point *X*. From a graphical standpoint the problem consists essentially in the simplification of certain pipe combinations to reduce the system into a problem similar to Case V; that is, pipes connected in parallel with an intermediate cross-connection.

[4] "Simplified Analysis of Flow in Water Distribution Systems," by J. J. Doland, M. Am. Soc. C. E., *Engineering News-Record*, Vol. 117, No. 14, p. 475, Fig. 1, October 1, 1936.

To use the graphical method, it is necessary to have definite flows through the system, which may be determined, however, upon a percentage basis. Since the use of the hydraulic slide-rule simplifies the computations if flows are expressed in terms of million gallons per day, this basis is adopted herein and the fire flow of 1 500 gal per min, which forms 45% of the total, becomes 2.16 mgd of a total of 4.8 mgd. The various "take-outs" at points along the mains are shown in Fig. 7 in percentages, which are converted to million gallons per day in the computations.

FIG. 7.—TYPICAL CASE II, FIRE FLOW SYSTEM AT POINT *X*

Three simplifications of mains are necessary to obtain two parallel pipes with an intermediate cross-connection similar to Case V. These are the mains between Points *D J*, *L O*, and *O R*. Between Points *D* and *J* there is a system consisting of two mains connected in parallel, Lines *D E G* and *D F G*, followed in series by Mains *G H I J*, with intermediate "take-outs." The simplification of these mains reduces the system, *D J*, to two mains connected in parallel, which requires the application of Case II to determine the losses of head from Points *D* to *J* under varying rates of flow.

Since the flow in any section of the main system will be unknown until the final solution, the computations and graphs must provide for a range of flows sufficient to include the various possibilities, with provision for subsequent "take-outs." Table 1(*a*) and Fig. 8(*a*) represent the computations and graphical analyses to determine the head-capacity relationship of the mains between Points *D* and *J*. The compound mains between Points *L* and *O* are similar to Case V with an intermediate "take-out," and the head-capacity relationship is determined as previously described. The computations and graphical representations are given in Table 1(*b*) and Fig. 9. Similarly, the mains between Points *O* and *R*, two mains connected in parallel, with intermediate "take-outs," are solved as given in Table 1(*c*) and Fig. 8(*b*).

Having simplified the main, *A B . . . S*, the final computations and graph can be determined. Table 2 presents the computations upon which the curves in Fig. 10 are based. As previously described in Case V, for a total flow of 2.16 mgd at Point *X*, the loss of head is found to be 116.5 ft, and the quantities and losses of head in the various main elements of the system will be as shown in Table 3. In explanation of the method of taking care of "take-outs," and to allow for the additional quantities through Lines *A W* and *A S* required for

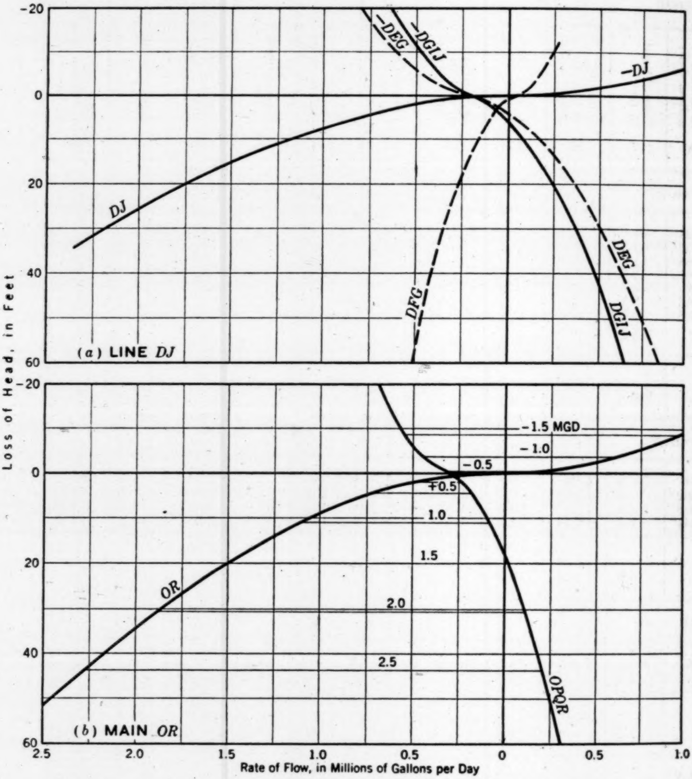

FIG. 8.—GRAPHS TO DETERMINE LOSS OF HEAD DUE TO FIRE FLOW AT POINT *X*

TABLE 3.—QUANTITIES AND LOSSES OF HEAD IN MAIN ELEMENTS

Description	Total	*A W*	*A S*	*W S*	*W X*	*S X*
Quantity, in million gallons daily	2.16	2.48	0.21	1.18	1.25	0.91
Loss of head, in feet	116.5	74.0	101.0	26.5	42.5	15.5

subsequent "take-outs," the curve for Line *A W* is moved to the right a distance equal to 1% of 4.8, or 0.048 mgd, and the curve for Line *A S* is moved to the left a distance equal to 10%, or 0.48 mgd, as shown in the dashed lines on Fig. 10.

The foregoing solution secures only one practical result—the loss of head in the system, under certain consumption requirements, with a definite fire flow at Point *C*. It is true that from this solution other flow and head losses can be computed by the $S^{0.54}$-relationship, but in this conversion the intermediate "take-outs" vary in the same ratio, a condition that occurs rarely in practical studies. The consumption in a system bears no relationship to fire flows, or to other extraordinary requirements. To secure the loss of head under any other fire flow with the same "take-outs," or the loss of head with the same fire flow

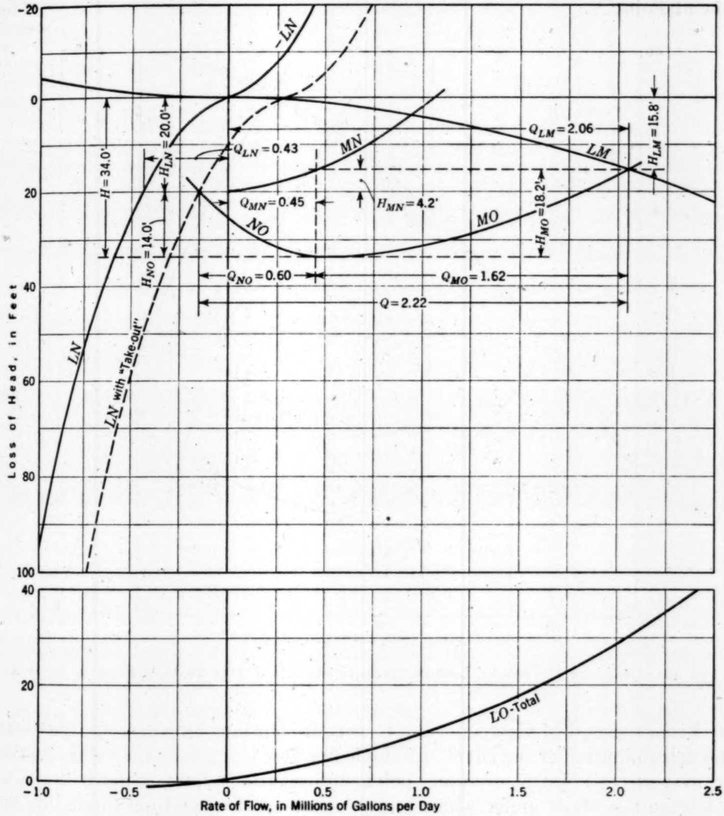

FIG. 9.—TYPICAL CASE II, LOSS OF HEAD, *L* TO *O*

under different consumption conditions, requires separate computations unless it is possible to construct a curve that will allow various flows to be taken through the system and the determination of losses of head without changing the quantities taken out. By obtaining various values of flow and corresponding head losses, a curve can be constructed from Fig. 10 which, the "take-outs" remaining the same, will give the head loss under any reasonable flow at Point *X*.

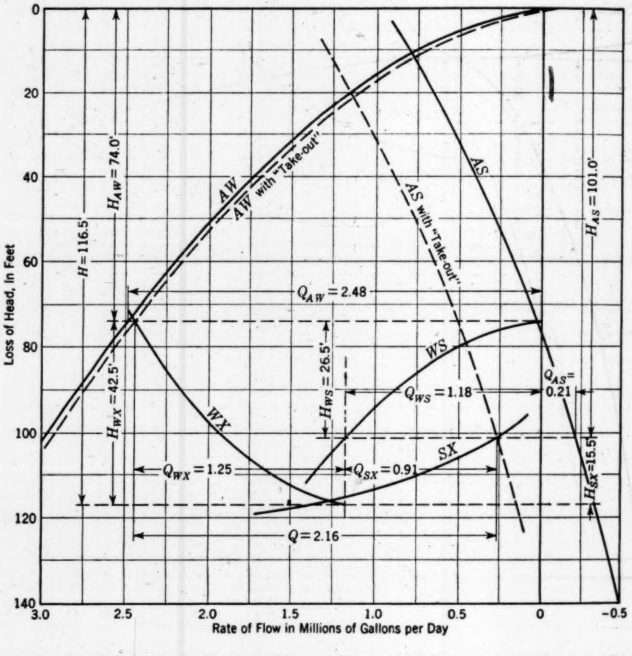

FIG. 10.—GRAPH TO DETERMINE LOSS OF HEAD IN MAIN *A X* DUE TO FIRE FLOW AT POINT *X*

From a practical viewpoint and to permit solutions for purposes other than the determination of the effect of a single fire flow (such as in the determination of pressures at Point *X*, or at any point, under various daily or hourly drafts, to calculate the heads under which pumps must operate, or to examine into the required capacity and height of storage), a slightly different analysis is of more value. For instance, let it be assumed that the rates of draft for ordinary domestic and industrial consumption vary from 1.5 to 3.0 mgd. If a series of capacity-head curves representing the loss of head under rates of 1.5, 2.0, 2.5, and 3.0 mgd are constructed, then, by interpolation, the loss of head under any flow and under varying rates of draft in the system can be secured directly.

To do this, four curves are constructed, representing losses of head through the system under rates of 1.5, 2.0, 2.5, and 3.0 mgd. In this analysis, the percentage "take-outs" are revised, as shown in Table 4, divorcing the normal consumption in the system from any extraordinary demands at Point *X*.

I	2	3.63	4	*T*	10	18.20	18				

Fig. 11 shows the head-capacity curves of the main lines which form the basis for the 2.5-mgd rate curve of Fig. 12. The latter shows four curves which give the head-capacity relationship for any flow from Point *X* under rates of 1.5, 2.0, 2.5, and 3.0 mgd, distributed through the system on the percentages shown in Table 4. By scaling the distances between the curves and the *Y*-axis, the losses of head for a flow of 2.0 mgd from Point *X* are determined, as follows:

Normal consumption, in million gallons per day	Loss of head, in feet
1.5	73.6
2.0	87.8
2.5	102.5
3.0	120.0

It is interesting to note in Fig. 12 that by scaling a distance on each rate curve equal to the same percentage of the total, a curve is constructed that may be termed a percentage curve, which can be extended, by the $S^{0.54}$-relationship, to any value. For instance, in the typical example, Fig. 7, the normal consumption in the system is 2.64 mgd. The extraordinary fire demand of 2.16 mgd is 81.7% of the normal consumption. Therefore, if a point is determined upon each rate curve equal to 81.7% of the normal consumption, a percentage curve, Fig. 12, is secured which, when expanded by the $S^{0.54}$ ratio, passes through the point, $Q = 2.16$ mgd, $H = 116.5$ ft, and an interpolated 2.64-mgd rate curve—the same solution as previously determined.

At their intersection with the *Y*-axis, these curves also show the loss of head in the system with no flow at Point *X*. Abscissas to the left of the *Y*-axis, therefore, represent "put-ins" which are required at Point *X* to satisfy the requirements of draft in the system. Furthermore, with the extension of these curves to the *X*-axis the abscissas of the intersections would represent the quantities that must be introduced at Point *X* to satisfy the normal drafts

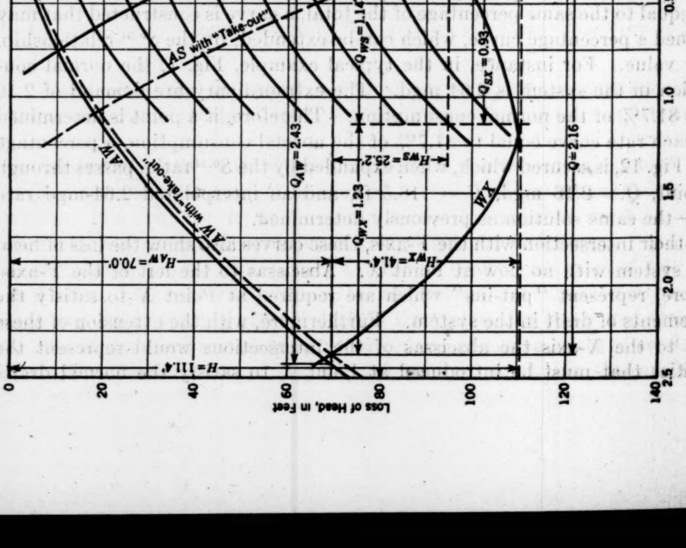

FIG. 11—TYPICAL CASE I; TOTAL LOSS OF HEAD; RATE, 2.5 MILLION GALLONS DAILY; VARYING DAILY DRAFT

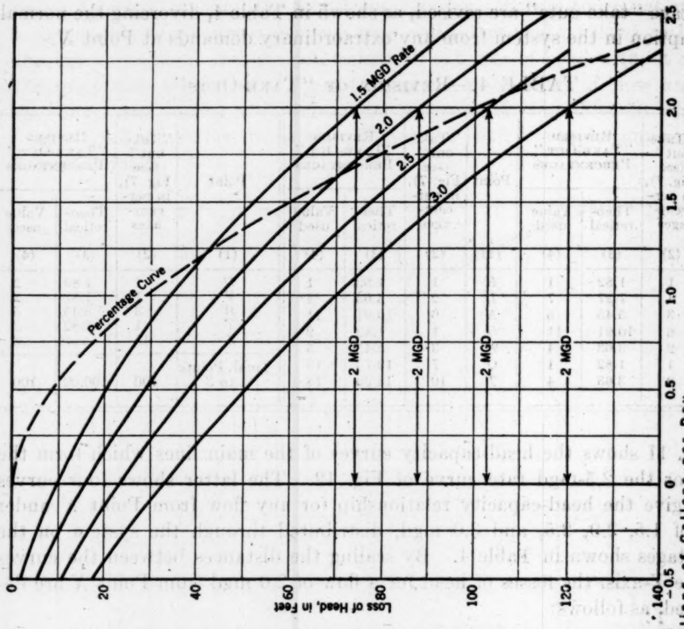

FIG. 12.—TYPICAL CASE I; LOSS OF HEAD IN LINE A X; VARYING DAILY DRAFT

and maintain Points *A* and *X* at the same hydraulic grade; that is, with no total loss of head between the two points.

From Fig. 12, it is possible to study the effect of storage at, or coming into, the system at Point *X*. For instance, if a curve is drawn on the left of the *Y*-axis to represent the loss of head in a main bringing water from storage, the hydraulic grades at Point *X* and at storage, and the flows from each source, can be obtained directly under varying rates of draft in the system. If the storage is variable in elevation, this curve will move, as required, up or down the *Y*-axis during the time interval being studied. In this manner the size and elevation of storage best suited for the requirements can be determined.

Having determined the losses of head in, and the quantities flowing through, the various elements, it is a simple matter to check back along the lines to determine the hydraulic grades at other points and to prepare a pressure contour map.

CONCLUSIONS

The graphical analysis of some of the common hydraulic problems arising in the design of the transmission and distribution elements of a water plant represents an approach to the solution of problems which, by their nature, contain so many variable factors as to cause most designers to hazard guesses upon the results which they hope to obtain, based upon premises which may be at wide variance with actual facts.

In spite of the great sums of money invested in these facilities, no element of a water system receives less attention in design than the transmission and distribution system. Proper consideration given to the correct interpretation of the data upon which the design of these elements must be based, and to a study of the hydraulics involved, in conjunction with field tests which are helpful in planning extensions or improvements to the system, will go far in providing adequate and efficient installations with a minimum outlay of capital.

DISCUSSION

Lynn Perry,[5] **M. Am. Soc. C. E. (by letter).**—The thorough manner in which the author has presented this subject certainly should be appreciated by the membership of this Society. For many years, the writer has solved problems of the nature herein presented by the time-worn analytic method. On many occasions, during this time, he has urged graphic methods for the solution of various types of problems. Such methods eliminate many errors, save time, and give a result sufficiently accurate for all practical purposes.

It appears that the upper parts of Figs. 2 and 3 show curves of parabolic form on rectilinear cross-section paper. If so, these curves would be straight lines when plotted on logarithmic cross-section paper and it seems as if some advantage might be gained from its use.

Frequently an old municipality having an inadequate water supply enlarges its supply by acquiring another, more abundant, at a higher elevation, and from an entirely new direction and source. A larger water main is likely to be installed, leading the new supply to the existing distributing system, sometimes under the direction of an engineer. In most such cases that have been brought to the writer's attention, the new line supplies the ordinary demand and overflows into the old intake. Only at periods of excessive demand is the old supply likely to be drawn down into the distributing system.

Charles M. Mower,[6] **Jr., M. Am. Soc. C. E. (by letter).**—The graphical approach to the problems of flow and loss of head in the elements of transmission and distribution systems is a method of analysis readily adaptable to a variety of problems. Mr. Aldrich has shown how the fundamental Freeman curves may be expanded to cope with the more complicated problems in water distribution which have too often been solved by guess.

With this, as with other office methods, however, there is the danger that the mathematical accuracy of the theory may hide inaccuracies in fundamental assumptions. Coefficients of carrying capacity, rates of flow, and rates of consumption, are often assumed, and the behavior of a pipe system is then analyzed by a flawless process of reasoning. However, the end result is in error because quantities that could, and should, be measured in the field were assumed.

Although one of the most usual assumptions is that $C = 100$ in the Williams-Hazen formula, a few loss-of-head tests on representative mains in a distribution system will show how far this assumption may be from the truth. Similarly, assumptions of flow, take-offs, or consumption may be too far from the truth to be of value, because these quantities are influenced by too many unknown factors. It is essential, therefore, to make actual field measurements instead of assumptions if the design of additions to a distribution system is to have a sound foundation.

---

[5] Asst. Prof., Hydr. and San. Eng., Lafayette Coll., Easton, Pa.

[6] With Glenn D. Holmes, Syracuse, N. Y.

The graphical method so clearly presented by Mr. Aldrich is of great value in determining how new mains and new storage facilities will affect a distribution or transmission system; but the analysis of flows and carrying capacities in the existing system should first be made by instrumental methods.

Thomas R. Camp,[7] M. Am. Soc. C. E. (by letter).—The adaptation of the graphical method of determining "equivalent pipes" to the solution of flow-distribution problems in complex networks, as presented in this paper, is not new. W. E. Howland,[8] Assoc. M. Am. Soc. C. E., has demonstrated that the Freeman method may be used for cross-overs and for simple networks similar to those in Fig. 6. The author seems to be the first, however, to demonstrate that accurate solutions may be obtained by this method for somewhat complicated water-distribution systems.

Three methods have now been shown to be practical for the analysis of flow in networks of a similar order of complexity to that of the network shown in Fig. 7. These methods are as follows:

(1) The "electric network analyzer" method[9];
(2) The Hardy Cross method[10]; and,
(3) The Freeman graphical method.

It should be pointed out that all these methods are "trial-and-error" methods of solving a large number of simultaneous equations. These equations are of three types, arising from three laws which may be stated as follows: (*a*) The algebraic sum of the rates of discharge toward any junction point is zero; (*b*) the algebraic sum of the head losses around any closed circuit is zero; and (*c*) for any pipe or system of pipes the head loss is directly proportional to some power of the discharge. The number of equations involved is so great that their direct solution algebraically is impracticable, even for simple networks. For example, in the single cross-over net of Fig. 5(*b*), eleven simultaneous equations are involved, five of which are exponential and the remainder linear.

Methods (1) and (2) may be classified as "controlled" methods; that is, the errors produced by successive trials become smaller. The Freeman method (Method (3)), however, appears not to be controlled. The solution is obtained by "juggling" the position of the curves that represent the elements in the system. The writer is at a loss to understand how one is to know in which direction to shift a curve when a large number of curves are involved. In the simple net of Fig. 6, consisting of two bays in each direction, four sets of curves must be adjusted. The distribution system represented by Fig. 7, although it involves a large number of elements, is less difficult to solve by the graphical method than the net of Fig. 6, because no stage of the solution of this system involves nets of more than one cross-over. It appears to the writer that a grid system consisting of numerous bays in each direction would not yield to solution by the graphical method except by chance.

[9] "Hydraulic Analysis of Water Distribution Systems by Means of an Electric Network Analyzer," by Thomas R. Camp, M. Am. Soc. C. E., and H. L. Hazen, *Journal*, New England Water Works Assoc., December, 1934, p. 383.

[10] "Analysis of Flow in Networks of Conduits or Conductors," by Hardy Cross, M. Am. Soc. C. E., *Bulletin No. 286*, Univ. of Illinois Eng. Experiment Station, November 13, 1936.

In Methods (2) and (3), the process consists of assuming a division of the flow at junctions and computing the corresponding head losses (or, conversely, of assuming the head losses and computing the corresponding flows). If the corresponding head losses do not conform to Law (*b*), an adjustment in the assumed flows is made and the process is repeated until the heads do conform reasonably well with this "head-loss summation" law. In Method (1), both Laws (*a*) and (*b*) are taken care of automatically. Since Ohm's electrical resistance law is not analogous to the hydraulic resistance law, adjustments must be made in the resistors representing the elements until the head-discharge (that is, voltage-current) relation conforms to Law (*c*). The number of corrections or adjustments required by both Method (1) and Method (2) will seldom exceed three. In both methods, with each adjustment, the errors in the assumed flows converge toward zero for nearly all the elements in a system. In the graphical method (3), one shift in the position of all the curves corresponds with one adjustment in the other two methods. A shift in the position of the curves, of course, is much more readily accomplished than is an adjustment by the other two methods; but a great many more than three shifts may be necessary and there appears to be no means of knowing that the shifts are being made in the right direction for a solution.

In comparing the three methods, the water-works engineer is interested in the relative lengths of time and amounts of equipment required. In the electric analyzer method, each element is represented by a resistance box. In preparing to solve a problem, the resistors must be connected to one another in a pattern similar to the water distribution system. "Put-ins" and "take-outs" are represented by leads from and to a battery or other source of electricity. Flow is represented by electric current and head loss by voltage drop. Hence, a scale ratio must be selected for conversion between the electric and hydraulic systems, and the proper range of resistance estimated for each element before the actual solution of a problem can be started. This preliminary work in Method (1) corresponds with the preparation of the curves representing the elements in Method (3). The analogous work in Method (2) consists only of computing a constant for each element which represents the relation of flow to lost head, all of which may be done on a slide-rule.

The solution of a problem by the electric analyzer method (1) consists of reading voltage and current for each element, and of adjusting the resistance so that the head (voltage) bears the proper relation with discharge (current). The readings and adjustments are quickly made. A solution by the Hardy Cross method (2) consists of assuming a division of flow at each junction, computing the corresponding heads, and then correcting the flows by an amount computed from the observed error in the heads. No equipment other than a slide-rule is necessary.

The time required to set up the electric analyzer for the problem represented by Fig. 7 was about 10 hr, and about 8 hr was required for the solution. The same problem solved completely by Method (2) occupied the writer for about 6 hr. J. J. Doland,[11] M. Am. Soc. C. E., states that in his solution of the same problem by the Hardy Cross method (2) only about 4 hr was required. It will be helpful if the author would give an estimate of the time required to solve this problem by the graphical method (3).

Harold E. Babbitt,[12] M. Am. Soc. C. E. (by letter).—Problems involving the hydraulics of flow in conduits in series, in parallel, or in a network, are commonly met in the study of water distribution systems. Problems involving the flow in conduits in series or in parallel, or in combinations of conduits in series and in parallel, have been subject for some time to accurate and practical solution by mathematical analysis but, until recently, no method has been available for the solution of problems involving cross-overs or networks; unless Mr. Freeman's graphical method[13] may be so considered. This method involves so much labor for the solution of a practical problem that it has not been widely used. The electrical analogy, introduced[14] in 1934 by Professor H. L. Hazen and Thomas R. Camp, M. Am. Soc. C. E., offers another method of solving such problems. It has not, however, been widely used, possibly because of the equipment required and its rather recent introduction. However, the author is not correct in his statement (see "Introduction") that "a mathematically accurate determination of the results to be expected in designing intricate grid systems or important reinforcements is impossible of attainment from a practical standpoint." Professor Cross' method for the analysis of flow in networks and conductors[15] makes it possible to solve such problems mathematically to any desired degree of precision, and results, using this method, are reported within 1% of accuracy by James J. Doland, M. Am. Soc. C. E. in his illustrative problem which the author has quoted.[4]

Until the publication of the Cross method problems involving the hydraulics of network distribution systems were most commonly solved by guesswork or by approximate methods whose results were little more than guesswork. The author's method is a simplification and an extension of Freeman's graphical method, which is applicable to some special conditions of flow in networks. It could probably be extended to include all possible problems in such networks.

Problems that may arise in a study of the hydraulics of a network distribution system may be illustrated on the simple cross-over diagram shown in Figs. 13(*a*) and 13(*b*), in which the diameters and lengths of all pipes are known. The principles are applicable to any number of pipes and cross-overs in the network.

Problems of Type I are illustrated in Fig. 13(*a*), in which all put-ins and take-outs are known, and it is desired to determine the distribution of flow in all the pipes and the pressures at various points in the pipe system. This can be solved by the Cross "Method of Balancing Heads."

Problems of Type III involve a combination of the conditions and unknowns in Types I and II.

The second type of problem is commonly met in water-works practice as, for example, where the pressures at a hydrant and at the pumping station, or at one or more distribution reservoirs, are known and it is desired to know the rate and direction of flow through the pipes in the distribution system. It is to be noted that where the Cross method is used for the solution of such a problem a change in one or more of the assumed pressures, put-ins, or take-

FIG. 14.—CONDITIONS OF FLOW FOR SOLUTION IN TABLE 5

outs, will involve the complete reworking of the solution, whereas if there is no change of the pipes in the distribution system, the problem resulting from changes in the conditions can be solved relatively easily by the method suggested by the author.

* See Fig. 14. † $n = 1$. ‡ Computation for $Q_F = 997$ (Fig. 14(*h*)) has not been included.

It is possible, however, that a number of problems, with successively slight changes in the conditions, might be solved by the Cross method, the results being plotted graphically with little or no more effort than would be involved in a series of solutions by the author's method. For example, let it be desired to determine the magnitude and direction of flow in each pipe in the simple cross-over system illustrated in Fig. 13(*c*). All the water enters at Point *A*; 500 gal per min is constantly taken out at Point *C*, and the take-out at the hydrant at Point *F* may vary between zero and 1 000 gal per min. The method suggested by Professor Doland has been used in this solution and, for simplicity, it has been assumed that $H = K\,Q^2$, in which *H* is the head loss in the conduit; *Q* is the rate of flow in the conduit; and *K* is a resistance factor dependent upon the length and diameter of the pipe. If the more commonly used Williams and Hazen formula were used here, the expression would be $H = K\,Q^{1.85}$. The computations involved in the solution are shown in Table 5 and Fig. 14, and the flows in each pipe, to the nearest 1% of accuracy, are entered in Table 6. These values can be plotted so that the rate of flow in any pipe, corresponding to any rate of flow from Point *F*, can be read from the curves. In Fig. 14, the underlined values denote relative resistances and the values in circles are the first assumptions of the percentage flow. The values beneath the circled numbers indicate corrections. The arrows in Table 6 indicate when the direction of flow in Fig. 13(*c*) is from left to right. When no arrow is shown the direction of flow is away from Point *A*.

Where added conditions are involved, such as storage reservoirs on the distribution system, or where the distribution system is on two or more levels, as on different floors of a multi-storied building, Professor Cross' method can be applied. There is no limit to the number of problems which may arise in the hydraulics of flow in a network distribution system. Any problem in this field can be solved by the Cross method and many problems can be solved by the author's method. Where both methods are applicable to the solution of a problem the choice will depend on the experience and the judgment of the computer.

Some confusion may result from the use, by the author, of the term, "hydraulic grade," to represent the piezometric head or the internal pressure at a point in a conduit. The term, "grade," is usually synonymous with "slope" rather than with "elevation" in most texts on hydraulics. The term, "pressure," or "head," would be more significant of the author's meaning.

C. Maxwell Stanley,[16] **Assoc. M. Am. Soc. C. E. (by letter).**—Being useful in the solution of the complex problems involved in the design of systems for the transmission and distribution of water, the method suggested by Mr. Aldrich is both interesting and valuable. Methods of design for such systems have had too little attention from water-works engineers, who have usually considered the design of a distribution system as something too complex for accurate computation, and yet too simple and practical to warrant much study. As a result, the art of designing transmission and distribution systems has developed slowly and has been out-distanced by the developments in supply, treatment, and conditioning of water. The distribution system is easily overlooked as it has usually grown bit by bit and seldom does the water-works man realize the accumulated investment that lies beneath the streets—out of sight and considered only when necessary.

The author's statement that the transmission and distribution "elements of a water system commonly exceed 50% of the total value" is conservative. Table 7, pertaining to distribution in several municipal water systems in Iowa, indicates an average of more nearly two-thirds and in only one case does the ratio drop below 50%, in spite of the varying size and types of supply studied.

TABLE 7.—Percentage of Total Investment in Distribution

The graphical solution outlined by the author seems to be much better suited to problems of transmission or distribution which involve not more than a few parallel circuits, than to complicated grids with numerous circuits or cross-connections. The solution of grids by the methods of Case VI is very ingenious, but is laborious and time-consuming as compared to the method devised by Hardy Cross,[17] M. Am. Soc. C. E. Indeed the example contained in the paper as a "Solution of a General Case" seems in itself proof that the Cross method is more quickly and easily applied to networks. The solution of this problem, as presented by J. J. Doland,[4] M. Am. Soc. C. E., is more concise and much quicker than the solution presented by the author. The graphical solution becomes too involved with a complicated grid. Furthermore, a grid or network is generally analyzed for a maximum condition, usually that of normal consumption plus a fire flow located at some particular point which, for the particular section of the system under consideration, will give the worst condition of pressure. Thus, usually one condition only is studied and the work required to prepare the curves for each section of pipe for the graphical method is excessive. This fact further tends to limit the usefulness of the method to transmission problems.

---

[16] Vice-Pres., Young & Stanley, Inc., Muscatine, Iowa.

[17] "Analysis of Flow in Networks of Conduits or Conductors," by Hardy Cross, *Bulletin 286*, Eng. Experiment Station, Univ. of Illinois, Urbana, Ill.

The graphical method appears well adapted to problems with varying rates of flow. In such cases, the curves for different pipes and groups of pipes present a visual analysis of the happenings with varying flows. Direct mathematical computation, on the other hand, presents only the answer for a given condition and the effect of varying flow is not so easily visualized.

The author's method is exceptionally well adapted to problems involving storage (similar to Case IV) and those involving transmission mains, interconnecting sources of supply, pumping stations, and storage reservoirs or tanks. In such problems, the graphical picture of the characteristics of the system permits a simple showing of water elevations, friction losses, and quantities which is extremely helpful. It seems to the writer that it is for problems of this type that the graphical method is best suited and will find its widest application and use. The method also has a value in that it may be applied to small sections of a large system when it is desired to obtain a clearer "picture" of the relationship of flow, friction, and head with varying conditions. Often, a chart or graph as a supplement to computations affords a better understanding of the situation.

The foregoing comments apply to the general usefulness and application of the method. A few comments may also be made on some of the details.

In the list of "Basic Data" required there should be added under Group (*d*)—which deals with storage—the item of depth of storage. Such depth plays a large part in the value of a given storage volume. The effectiveness of a given total volume in an elevated tank, as compared to the value of the same volume in a stand-pipe, is a good example of the need for considering depth of storage as an important factor.

Conversion factors for various values of C in the Williams-Hazen formulas for application to the friction losses obtained from Fig. 1 ($C = 100$), are, as follows:

C	Correction factor	C	Correction factor
70	1.94	110	0.84
75	1.70	115	0.77
80	1.51	120	0.71
85	1.35	125	0.66
90	1.21	130	0.62
95	1.10	135	0.58
100	1.00	140	0.54
105	0.91	145	0.50
		150	0.47

Conversion factors may be more readily obtained from such a list than from the extra curves, in Fig. 1, showing the relationship of $S^{0.54}$ and $S^{\frac{1}{0.54}}$.

Warren E. Wilson,[18] Jun. Am. Soc. C. E. (by letter).—An interesting application of graphical methods to the solution of problems encountered in the design of water distribution systems, is presented in this paper. It is claimed for the method that in certain cases better progress can be made than with mathematical methods or by trial and error. It is not entirely clear which cases are in this category. Since the purpose of the graphical solution is avowedly to obtain a practical result in a short time it should be on the basis of this purpose that it be compared with other methods. Great accuracy is not required; nor can it be expected, since the basic assumptions one makes are necessarily merely approximations. Hence, any of the methods may be expected to give results that have the required degree of accuracy.

It appears that the preliminary process through which one must go, namely, that of plotting curves to suitable scales, necessarily consumes considerable time. In addition, one must adjust a number of curves to the proper positions to obtain the desired results. This adjustment is doubtless made with greater speed as one gains experience in the method, but must nevertheless take considerable time. The fact that considerable experience is required to use the graphical method to advantage then appears to be an undesirable feature of the method since it is possible to teach the Cross method to a group of students and develop in them sufficient skill to handle complex networks in a period of not more than a week. It would be difficult to develop the same proficiency in the graphical method in a similar period of time. From the standpoint of the professional engineer the need for an experienced designer in the manipulation of such a method is a disadvantage since the work could be delegated to an inexperienced person after giving him just sufficient instruction to enable him to handle the method of successive approximations as a routine set of calculations.

It is the writer's belief that if one acquaints himself fully with the fundamentals of the Hardy Cross method[4] and clears away any false notions he may have about a method of successive approximations in the question of accuracy, he can solve even the most complicated network problems in a comparatively short time. There can be no question that the preliminary preparation required in the Cross method is far less than that required for the graphical method, since it involves only the calculation of a constant for each section of pipe in the network. The actual work that is necessary in making the successive approximations is certainly no more difficult and requires very little time.

The writer would be interested in a statement of the particular types of problems in which the graphical method is believed to be superior to the Cross method.

Harold K. Palmer,[19] M. Am. Soc. C. E. (by letter).—The method of handling complex problems in water supply design, which is presented in this paper, well merits the careful study of all who have similar problems to solve, and the author deserves praise for the ingenious manner in which he has solved some of the worst of them. The writer has used the same method in handling pumping problems, which the author mentions, for several years and has found it a very convenient tool. The following comments are offered to supplement the author's handling of the subject and to emphasize the fact that it is a method which can be used for many purposes, depending largely upon the ingenuity of the engineer.

One fact that should be especially emphasized is that there is nothing obscure or complex about it. Instead of trying to solve algebraic formulas of the second or higher degree by computation the designer simply plots the curves, combines these curves, and the intersections give the solution desired. Thus, the solution of the problem is no more difficult than the drawing of the curves. It is only necessary to keep in mind the factors that produce loss of pressure and to apply them in the right places by simple methods. The principal way in which it differs from the ordinary computation is that the latter is performed for one pressure or one value of Q, and if the result is not correct another approximation must be made. In the author's method all values of pressure and Q within certain limits are considered and the solution is given at once by the intersection of certain lines.

Fig. 1 was prepared probably from the Williams-Hazen tables, which is also the writer's method of making similar drawings, but these tables give only standard cast-iron pipe sizes, and other sizes must be interpolated. This can be done very easily by the following method, which is applicable to any similar exponential formula. Fig. 15 is a simplification of Fig. 1 showing only a few of the lines to avoid confusion, and yet show the method. Marking the intersections of the line for 20-in. pipe with the 20 ordinate, the 30-in. pipe line with the 30 ordinate and the 60-in. pipe line with the 60 ordinate, it will be noted that all the intersections marked are on the same straight line, which can be called the interpolating line. Why this should be a straight line can be proved by any one mathematically inclined, but it is not required in this case, and it is easier to draw lines for two or three sizes of pipe and join the proper intersections than to compute the slope of the intersecting line. To interpolate any other size of pipe it is necessary only to note the intersection of the interpolating

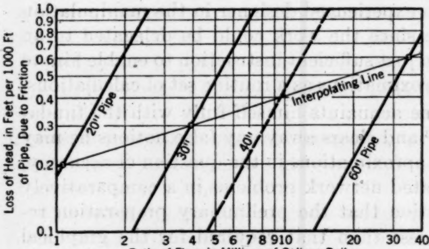

FIG. 15

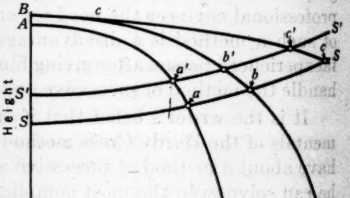

FIG. 16

line with an ordinate corresponding to the diameter required, and draw through this intersection a line parallel to the other pipe curves. Thus, any size of pipe can be interpolated without difficulty and in much less time than it takes to find the values in a table and plot them. Furthermore, a graph for metric sizes could be computed from the data for English sizes.

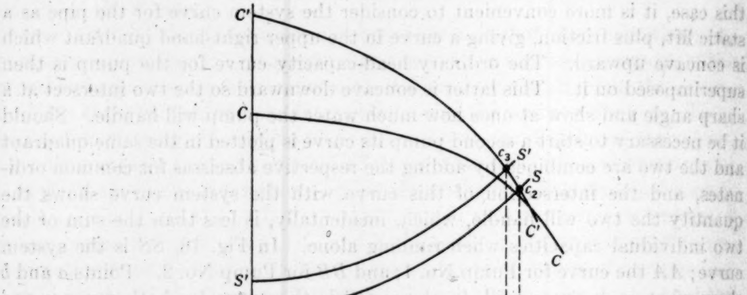
Several manufacturers of centrifugal pumps are using a method similar to that of the author to show the behavior of pumps on a given pipe system. In this case, it is more convenient to consider the system curve for the pipe as a static lift, plus friction, giving a curve in the upper right-hand quadrant which is concave upward. The ordinary head-capacity curve for the pump is then superimposed on it. This latter is concave downward so the two intersect at a sharp angle and show at once how much water the pump will handle. Should it be necessary to start a second pump its curve is plotted in the same quadrant and the two are combined by adding the respective abscissas for common ordinates, and the intersection of this curve with the system curve shows the quantity the two will handle, which, incidentally, is less than the sum of the two individual capacities when running alone. In Fig. 16, *SS* is the system curve; *AA* the curve for Pump No. 1; and *BB* for Pump No. 2. Points *a* and *b* show what each pump will do alone; *CC* is the curve for both pumps; and Point *c* gives the quantity of flow that the two will handle.

If the pumps are discharging into the bottom of a tall stand-pipe in which there is considerable fluctuation in the height to be pumped, it is advisable to draw another curve for the stand-pipe full, such as Curve *S′S′*, Fig. 16, in which the height, *SS′*, is the increased depth. Points *a′*, *b′*, and *c′* now show what the pumps will do as the stand-pipe fills.

Should the system consist of two or more pipes in parallel they can be added to the diagram in a similar manner and the saving in head, and increase in output of the pumps, is shown at once.

The foregoing method serves very well where the pumps are close together and the individual suction losses are small in comparison with the discharge head. It is obvious that if two 1 000-gpm pumps are running in parallel the friction back of the junction of the two is no more for both pumps running than it is for only one. In fact, it is rather less because each alone might pump 1 100 gpm and only 1 000 gpm when both are running.

For a comprehensive case consider two deep-well pumps, *A* and *B*, Fig. 17(*a*), separated several hundred feet, both feeding into the suction of a booster pump, *C*, near Pump *B*, which forces the water into a high stand-pipe far enough away to offer some appreciable pipe friction, and subject to an increase in depth with its equivalent increased pumping lift; also let the standing water surface in the two wells be at the same elevation but with different draw-down characteristics for each. To avoid too many overlapping lines in Fig. 17(*b*) the two well pumps are shown in different quadrants. The distance from the static water surface to the suction of the booster pump, *C*, is *OO′*. As water in Well *A* draws down, this lift increases along the line, *O′w′*. The suction losses and pipe friction to Pump *C* for Pump *A* are shown by Curve *Of′*, and the total lift and losses for Pump *A* are shown by *O′t′*. Arc *AA* is the head-capacity curve for this pump, and subtracting (vertically) *O′t′* from Curve *AA* gives Curve *aa* which represents the elevation at which Pump *A* will deliver various quantities of water to Pump *C*. A similar system is shown for Pump *B* in the right-hand quadrant, *ab* representing the elevation at which Pump *B* delivers water to Pump *C*. Adding *aa* and *ab* horizontally gives Curve *a–ab* which is the corresponding curve for the two running in parallel. Curves *SS* and *S′S′* represent the system curves for the stand-pipe empty and full, respectively, and *CC*



(*a*) PROFILE OF PIPE LINE

FIG. 17.—LOSS OF HEAD, IN FEET PER THOUSAND FEET OF PIPE, DUE TO FRICTION

is the head-capacity curve for Pump *C*. Adding (vertically, since the two are now in series) Curves *a–ab* and *CC* give Curve *C′C′*, the combination curve for all pumps, intersecting the system curves at Points c_2 and c_3, which represent the quantities pumped when the stand-pipe is empty and full. Lines drawn vertically from these points to Curve *a–ab*, and then horizontally to Curves *ab* and *aa* with vertical lines from these intersections to Curves *AA* and *AB*, show at Points A_2 and A_3, and at Points B_2 and B_3 how much each well pump is handling, and if it is working at its best efficiency.

The theory on which this method of attack is based is that the pump adds pressure to the water, which pressure is reduced at any point along the pipe by the static lift plus the friction. These respective losses are charged against each pump at the junction point where it is obvious that both must be exerting the same net pressure, and the combined flow will be the sum of the flows corresponding to this net pressure. Since there was only one booster pump and no complications it was not necessary to use the same method on it, although it could be done if so desired.

This method of analysis is very useful in investigating low-head complex pumping systems and easily solves some very difficult problems with remarkable accuracy.

F. KNAPP,[20] ESQ. (by letter).—In 1936, the writer was called upon to investigate the pressure and flow conditions of the water supply and fire protection system of an important Brazilian chemical plant where interruption of the flow of water would lead to disastrous results. It was especially desired to know the effect of shutting off, quickly, certain flow demands for production purposes. As a prerequisite to this extensive surge investigation (by the graphical method), the flow and the resulting head losses in the system for steady conditions had to be found, and a graphical method, first published by Spiess,[21] was used and extended for the requirements of this specific problem. As far as the author's Case V is concerned, the graphical solution as proposed is far simpler and more general than the method used by the writer, a combination of graphical and analytical procedures.

The author is to be commended heartily for his timely paper which is of considerable interest to all hydraulic engineers engaged in problems of water flow in pipes. It is only too true that the design of the transmission and distribution system receives little attention in spite of the great sums of money invested in such installations. The rational method proposed by the author makes it possible also to decide at once whether certain cross-connections are essential and of decided benefit. In the investigation made by the writer, considerable savings were effected by removing several long pipes connecting points of about equal, or slightly different, pressure.

At first glance, the paper seems more complicated than it really is. The discharge-head relations for the solution of the several fundamental cases are plotted, using tables or any other appropriate means. Furthermore, it is not necessary to make Table 1 as complete as the form presented by the author. It is sufficient and facilitates the work to record only the results of the simplified layout, such as, for example, "Total, *D* to *J*."

As far as the solution of the case presented in Fig. 12 is concerned, the author did not make it clear that, actually, four diagrams of the type shown in Fig. 10, drawn for the various flow demands in the system, are required; and only when the writer realized this point, did he understand the solution.

Except for this minor criticism, the paper deserves to be mentioned as essential to the art of hydraulics, and the writer hopes that its contents will come to the attention of authors of books on applied hydraulics, who too often do not pay enough attention to professional papers representing an advance in the art.

WESTON GAVETT,[22] ASSOC. M. AM. SOC. C. E. (by letter).—In so far as it demonstrates the application of Mr. Freeman's method to the solution of complicated pipe systems, the paper by Mr. Aldrich is most interesting. By showing the application of the graphical method, first to simple typical problems and then to a more complicated system, the author clearly demonstrates the method and advantage of this procedure. Its advantage is the use of natural co-ordinates for head and flow, permitting the graphical summation of these values.

Celluloid sheets described by the author are convenient and may be easily prepared by rubbing the surface of commercial celluloid with an ink eraser.

Although the author mentions the hydraulic slide-rule as an easier means of solving simple problems than the graphical method, he gives no details as to the slide-rule procedure so that the reader may compare the two methods. In stating that "a mathematically accurate determination * * * is impossible of attainment from a practical standpoint," he is correct. This statement, however, tends to encourage rather than dispel the current opinion that, until 1935, it was impossible to design a distribution system. To assume that for years water-pipe systems have been designed by guesswork is extreme.

The computation of the losses in a distribution system that may be checked by actual tests to an accuracy greater than the precision of the basic data should be sufficiently accurate for all except academic purposes. Such computations may be made and have been made with the hydraulic slide-rule at least since 1905.[23]

ELLWOOD H. ALDRICH,[24] M. AM. SOC. C. E.—The helpful comments offered in the discussion of this paper are appreciated. In many of the discussions, as well as in previous papers, the writer is surprised to note the general admission that practical solutions of these problems were impossible prior to the Camp-Hazen and Cross methods of analyses. The writer has used the graphical method presented in the paper over a period of more than ten years in many involved problems and has quite successfully checked his computations by the results obtained after the completion of several construction projects.

The discussions have been devoted largely to comparisons of the three methods of analyses, namely, the Camp-Hazen method, the Cross method, and the graphical method presented in the paper. In general, they have been restricted to the solution of distribution networks. In explanation, this paper was prepared and submitted prior to the publication of the Cross method. Typical Case II was substituted for a more general case in the final revision of the paper to secure a better comparison of the three methods of analyses.

[23] "Hydraulic Tables," by Williams and Hazen, 1905.

[24] Associated with Reeves Newsom, Cons. Engr., New York, N. Y.

The discussions, therefore, have been concerned largely with subsequent developments in the solution of grid-system problems.

The method of analysis to be used in solving the various types of problems is only a means to an end. The choice of method, the Cross or the graphical (the Camp-Hazen method is essentially similar to the Cross method), will be governed principally by the purpose of the problem, its complexity, and the familiarity of the designer with the two methods. In intricate grid-system problems the Cross method more readily effects a simplification of the problem. In simple transmission studies, such as may be termed Typical Case II, and in storage and pumping studies, the graphical solution appears simpler and more adaptable to a portrayal of the varying conditions usually present in a problem. In most problems a combination of the two methods would appear desirable. As the intricacy of network problems increases, so does the labor of solution, by any method.

The variation of the Cross method, suggested by G. M. Fair,[25] M. Am. Soc. C. E., further simplifies the mechanics of the Cross method, permitting the use of the hydraulic slide-rule and making unnecessary the compilation of a pipe resistance table.

Professor Perry has pointed out that the use of logarithmic paper in the graphical method would result in straight lines instead of curves. This is true, but in the more complicated problems, involving "take-outs," "put-ins," varying elevations, and interconnecting pipe, the measurements of head and quantity are made more difficult, so that a rectilinear scale is to be preferred.

The value of Mr. Mowers' comments in stressing the field investigation of drafts and carrying capacities of pipe is very evident. When *C* varies from 100 to 80, the resulting friction losses are increased by 50 per cent. To one who has had experience in measuring coefficients and flows it is apparent how illogical, and even absurd, it is to attempt to make an office design within an accuracy of 1% or 2% unless the data upon which the design is based can be determined with reasonable accuracy. However, assumptions of draft, distribution of consumption, and carrying capacities of pipe are, and always will be, required when designing for future works. Judgment must be tempered with a knowledge of field variations when making these assumptions and a proper balance maintained between the desirable accuracy of the several parts of the problem.

Professor Camp has summarized some of the comparative advantages and disadvantages of the three methods of analyses as they are applicable solely to network problems. It appears that the electrical analogy method, because of the time and extensive equipment required for the solution of a simple problem, has no advantage over the Cross method. It is questionable whether an intricately connected grid system requires elaborate and time-consuming methods of analyses, except as an academic problem. In many cases a judicial combination of mains and "take-outs" will not materially affect the accuracy of the result. Typical Case II, as first solved by Professor Camp by the electrical analogy method, prompted this paper. When this example first appeared,[26] an answer to the problem was secured by the graphical method, within 2% of the accuracy of the final result, in less than 2 hr, using an hydraulic slide-rule and a piece of co-ordinate paper. This naturally prompted the query as to the necessity for the extensive equipment, time, and energy required for the solution of the problem by the electrical analogy method.

---

[25] *Engineering News-Record*, March, 1938, p. 342.

In presenting the problem of Typical Case II more time was consumed in order to present the method of analysis clearly. Approximately four hours were required to secure the answer to the problem with the accuracy determined. In the actual design of such a system several short-cuts are possible to one familiar with the graphical method since the shape of the curves give a picture of the problem. It is immediately apparent that the loops *DJ*, *LO*, and *OR* (Fig. 7) can be approximately simplified with very little effect upon the final accuracy.

Irrespective of the fact that the statement: "A mathematically accurate determination * * * is impossible of attainment from a practical standpoint" was submitted before the writer knew of the Cross method (a statement to which Professor Babbitt takes exception as being incorrect), it is a fair statement in its broader sense when the variations in consumption rates and coefficients, which obtain in practical application, are considered. With certain assumed conditions, it is true that any of the methods of analyses can give a mathematically correct solution. The results secured in practical application, however, may be at wide variance with the solution due to inaccuracies of assumptions.

As illustrated by Professor Babbitt, the Cross method can be used, with graphical assistance, to cover varying conditions without repeating all computations.

Mr. Stanley has clearly presented the various fields in which each method of analysis might be the more applicable. In determining the influence of storage, as he points out, the depth—or rather, the effective range and elevation of storage—must be considered.

It is questionable whether (as intimated by Professor Wilson) the adaptability of a method of solving engineering problems should be measured by the speed with which students can be taught the mechanics of using it, unless, at the same time, they obtain a proper appreciation of the fundamental theory. Any short-cut method of solving the type of problem considered in the paper is too susceptible to misuse without an understanding of the underlying theory and conditions which actually affect the problem in practice.

With a knowledge of the use of the hydraulic slide-rule the plotting of the head-capacity curves is a relatively easy and quick process. The adjustment of the curves of an intricate network becomes more difficult as the intricacy increases and, unquestionably, in the more difficult problems of this nature the modified Cross method is to be preferred. In general, such problems are not so important to the practising engineer as those pertaining to storage, pumping, and transmission, wherein the flow and head conditions are constantly varying. It is in such types of problems that the ability to allow for the varying conditions by the simple process of moving a curve indicates an advantage of the graphical method. As a knowledge of this method of solution increases, the picture which the curves portray by their shape immediately indicates the conditions which are, and those which are not, important.

---

[26] *Journal*, New England Water Works Assoc., December, 1934.

A further example of the use of graphics in the solution of pumping problems is clearly presented by Mr. Palmer. The scope of the paper was limited to the presentation of the basic cases. The writer, however, has used the graphical method almost exclusively in pumping studies involving the centrifugal pump, since the head-capacity curve of such a pump is similar to that of a pipe line and a combination of the two is easily effected.

It is true, as pointed out by Mr. Knapp, that the presentation of the cases in the paper are more complicated than they need be in the actual use of the graphical method, but it appeared desirable to present them in a comprehensive manner. In actual use many short-cuts are possible to an experienced designer.

To combine pipe connected in series and pipe connected in parallel, or combinations of the two, it is unnecessary to draw curves for each piece of pipe and combine them graphically. In answer to Mr. Gavett, series-connected pipe of any number, without take-outs or put-ins, can be combined directly by making an addition of the head losses in each pipe determined for each flow from the hydraulic slide-rule and plotting the composite pipe directly. In parallel-connected pipe, the head loss is first assumed, the quantities each pipe will carry under the assumed head loss is added, and the composite curve drawn. Cases I and II of the paper were included only to illustrate the fundamental theory.

The use of the graphical method of solution of some of the distribution and transmission problems of water supply alone or in combination with the Cross method evidently permits more accurate and economical solutions of such problems than have hitherto been generally possible.

AERATION TANKS FOR ACTIVATED SLUDGE PLANTS

By S. W. Freese,[1] M. Am. Soc. C. E.

With Discussion by Messrs. Norval E. Anderson, Weston Gavett, and S. W. Freese

Synopsis

The design of aeration tanks in which diffused air is used for aeration, as differentiated from tanks with mechanical, surface aeration apparatus, is treated in this paper. An endeavor has been made to present the bases of theory and practice governing the design of the principal elements of diffused-air aeration tanks. The derivation of practicable bases of design has been made possible by the wealth of research, experimental, and plant-operation data which have been made available during the past few years particularly through the work of such agencies as the Sanitary District of Chicago.

Introduction

The results of experiments and plant-operation data offer rational bases for the design of the elements of diffused-air aeration tanks for the activated sludge process. Experiments run in parallel, with one element varying as between two experimental units, and plants that are adjusted to optimum operating conditions, are particularly good design guides.

The required capacity of the tanks depends upon quantity of sewage, aeration period, and percentage of return sludge. The results at plants and experimental units treating sewage of widely varying strengths indicate that the minimum aeration period and optimum percentage of return sludge vary with the strength of the sewage being treated. Parallel experiments with aeration tanks, 10 ft and 15 ft deep, indicate that between these two depths the economic depth of tank may be determined by balancing the cost of compressing air against fixed charges on tank cost. Experiments at Chicago, Ill., show that a ratio of tank width to tank depth of 2 to 1 may be used safely.

Note.—Presented at the meeting of the Sanitary Engineering Division, New York, N. Y., January 16, 1936, and published in October, 1937, *Proceedings*.

[1] Cons. Engr. (Hawley, Freese & Nichols), Fort Worth, Tex.

Data from a number of plants indicate that, except possibly in the case of some unusual trade wastes, the quantity of air required is approximately 0.0045 cu ft per gal of sewage per ppm of 5-day bio-chemical oxygen demand (B.O.D.) removed over-all by plants using air-diffusion aeration tanks of the spiral-flow type. The "spiral-flow" type of tank requires less air than the "ridge and furrow" type, and the combination of air diffusion with mechanical agitation of the paddle-wheel type offers a further possibility of material savings in both air and total power required. The data from a number of plants indicate that the quantity of air required for "complete treatment" is independent of the degree of preliminary sedimentation and that plants with no preliminary sedimentation require no more air, in parts per million of over-all bio-chemical oxygen demand removal, than plants with preliminary sedimentation.

In the matter of tank details the use of deflectors placed longitudinally at corners of the aeration channels is now standard practice. Recent experiences indicate that diffusers with permeabilities of from 35 to 45 may be used safely, and that the size of the air bubbles does not differ appreciably from those diffused from plates of lesser permeability. The plates of higher permeability do not clog as readily, and they offer less resistance to the flow of air than plates of lower permeability (15±) which have been used in the past. Cement grout for jointing diffusion plates into plate containers is still common practice. The development of corrugated rubber gaskets with clips for holding the plates in place offers a possibility in overcoming the objection to cement grout joints which prevent the removal of plates intact.

HISTORICAL

In his classic "Modern Methods of Sewage Disposal," published in 1894. Mr. George E. Waring, Jr., devoted a chapter to "Filtration with Aeration," in which he reviewed the work done prior to 1894 in the matter of the aeration of sewage. Mr. Waring concluded the chapter with the following prophetic statements:

> "Probably if a mass of sewage could be held in a state of continual effervescence, due to injected air, for a sufficiently long time, its organic matter would be as completely oxidized as it would be in the best-regulated filtration; as it is, indeed, in a rapid river, after a certain period of flow. It is also conceivable that a deep and narrow channel, with an air-supply at its bottom, would purify a slow stream flowing through it for a practicable distance. It seems likely, however, that air introduced under pressure would be much more economically used in the pores of a coarse filter than in a freely moving body of liquid, through which it would rise in bubbles so rapidly as to come less completely in contact with the suspended and dissolved matters.
>
> "This whole subject is still in a speculative stage, and it is introduced here chiefly with a view to suggesting further investigation in an interesting and promising field."

The later development of the activated sludge process of sewage treatment and more recent experiences in the design of aeration tanks have confirmed the wisdom of these early statements.

Early experiments with the aeration of sewage prior to the development of the activated sludge process of sewage treatment may be conveniently reviewed in the first chapter of "The Activated Sludge Process," (1927), by Mr. A. J. Martin. In 1914 and 1915 Messrs. Edward Ardern and William T. Lockett described, in a series of three papers read before the Manchester (England) Section of the Society of Chemical Industry, their experiments which are generally credited with having originated the activated sludge process of sewage treatment. Messrs. Ardern and Lockett gave credit to Mr. C. J. Fowler for his suggestions which led to, and were followed in, the making of the activated sludge experiments.

The process was patented by Jones and Attwood, Limited, Stourbridge, England, in a series of patents taken out in 1914 and 1915 in England and later perfected in the United States. Messrs. Jones and Attwood designed the first activated sludge plant of any size (approximately 900 000 U. S. gal per day) in 1916, at Worcester, England, part of an existing sedimentation tank being converted into aeration and sludge settling tanks. The aeration tank consisted of a battery of five channels, 8 ft wide by 80 ft long, 17 to 18 ft deep (water depth), and with three vertical under-flow baffles in each channel. Air diffusion was of the transverse ridge and furrow type with rows of diffusers at 5-ft centers in the first channel and at 10-ft centers in the remaining channels. The ratio of air diffuser area to tank area was approximately 1 to 10. The sewage passed through the channels in a modified "endless channel" type of continuous flow, at the end of each channel a portion of the flow being carried back by induced circulation into the preceding channel.

Laboratory experiments at Manchester were followed by the installation of an activated sludge sewage treatment plant at the Withington Sewage Works of the Manchester Corporation, this plant being placed in operation in September, 1917. The Withington aeration tank was constructed by converting a part of an existing sedimentation tank, approximately 20 ft by 100 ft, into a series of five channels, 4 ft wide and 100 ft long, with 5.5-ft water depth over diffusers. The tank was of the series, "once through," continuous flow type. The floor was laid out in transverse ridges and furrows, the slopes of the ridges being at 35° with the horizontal, and the air being introduced through rows of diffusers placed in the furrows, on 6.75-ft centers. The diffuser area amounted to one-seventh of the aeration tank area or the water surface area. This plant successfully treated 440 000 gal (U. S.) of domestic sewage per day. At another Manchester Corporation plant, the Davyhulme Sewage Works, the "spiral-flow" type of aeration tank was first used, the plant being put in operation in 1921. The aeration channels at Davyhulme are 8 ft wide by 9 ft deep (water depth) with diffusers along one side of the channel at the base of the curved footings of division walls; the ratio of diffuser plates to tank area is approximately 1 to 18. The plant has a rated capacity of 1 200 000 gal (U. S.) per day.

During 1915 a number of experiments with the activated sludge process were initiated in the United States, notably at Champaign, Ill., Lawrence, Mass., Baltimore, Md., Milwaukee, Wis., Brooklyn, N. Y., Chicago, Ill., Houston, Tex., and Cleveland, Ohio.[2] Based upon the experimental work at Houston and Milwaukee, Mr. E. E. Sands designed two large activated sludge plants for Houston. The North Side Plant at Houston, with a nominal capacity of 10 000 000 gal per day, was placed in operation in May, 1917, and the South Side Plant, with a nominal capacity of 5 000 000 gal per day, was placed in operation in August, 1918. These two plants were the largest activated sludge plants in operation until 1925 when the Milwaukee and Indianapolis plants were placed in operation.

---

[2] *Proceedings*, 1916 Convention, Am. Soc. of Municipal Improvements.

The Houston aeration tanks consist of four units at the North Side Plant and two units at the South Side Plant. Each aeration unit consists of two channels, one 18 ft wide and the other 9 ft wide, of a length of 280 ft and a water depth over diffuser plates of 9.75 ft. The bottoms of tanks are of the sawtooth ridge and furrow type with rows of plates at 5-ft centers, the individual plates being spaced so as to give a ratio of diffuser-plate area to tank area of 1 to 7. For several years the plants were operated as the continuous flow, "endless channel" type, with a ratio of incoming raw sewage to circulating mixed liquor of from one-third to two-thirds; however, the North Side Plant has since been enlarged and remodeled as a "once through" type with provision for the reaeration of return sludge.

The successful operation of the pioneer activated sludge sewage treatment plants, such as those at Manchester, Houston, and Worcester, along with the extensive experimental work at Chicago, Milwaukee, and Indianapolis, and elsewhere, not only firmly established the activated sludge process, but also gave a fairly rational basis for the design of aeration tanks and the other principal features of activated sludge plants.

Aeration Tank Capacity

The first step in the design of aeration tanks is to determine the required capacity. This capacity depends upon three factors: (1) The quantity of sewage to be treated; (2) the percentage of return activated sludge; and (3) the aeration period or time of detention of the mixed sewage and activated sludge liquor in the aeration tanks. Design data for aeration tanks have necessarily been related to the average daily sewage flow, and the writer has used that basis in considering the various factors involved. The average daily sewage flow is a practical basis of design for works treating the average domestic-industrial sewage collected in separate sewer systems. The ratio of maximum hourly flows to daily averages may vary considerably without disturbing the activated sludge process, due to the capability of the sludge to store "biological energy."

Other factors being constant, the length of the aeration period depends primarily upon the quality of the sewage to be treated and the degree of treatment required. Fig. 1 is a typical curve showing the relationship between the aeration period and the degree of purification, the latter being measured after clarification of the mixed liquor. For a particular sewage this curve will vary with the percentage of return activated sludge, mixed with the sewage, the character and biological activity of the sludge, the kind and intensity of aeration, the time and type of clarification, temperature, and other factors of less importance.

During the first stage of the aeration period the impurities in the sewage are rapidly coagulated and adsorbed by the activated sludge, and the rate of coagulation adsorption during this first stage is proportional to the percentage of biologically active sludge in the mixed liquor.[3] After the initial coagulation adsorption has taken place, the purification of sewage, measured in terms of bio-chemical oxygen demand, proceeds at the much slower and fairly uniform rate of oxygenation of the mixed liquor. During this second stage the presence of a large proportion of sludge probably retards the oxygenation of the sewage proper because of the relatively greater oxygen requirements of the sludge.[4] The oxygenation of the mixed liquor during both stages, and of the sewage during the second stage, no doubt proceeds in accordance with the law expressed by E. B. Phelps: "The rate of biochemical oxidation of organic matter is proportional to the remaining concentration of unoxidized substance, measured in terms of oxidizability." [5]

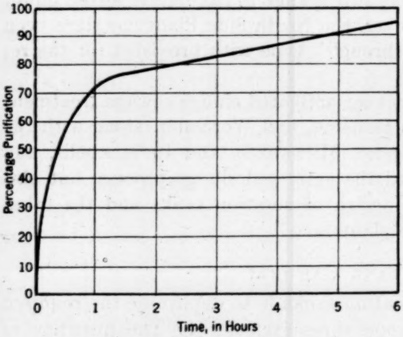

Fig. 1.—Relationship Between Aeration Period and Degree of Purification

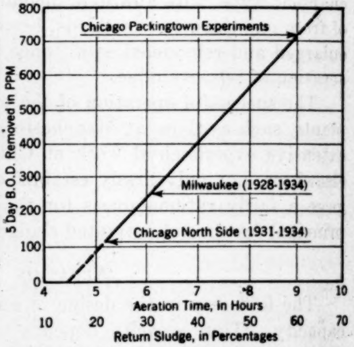

Fig. 2.—Relation Between 5-Day B.O.D. Removal and (1) Aeration Period, or (2) Percentage of Return Sludge

For "complete treatment" the minimum aeration period varies with the strength of the sewage. To show this relationship the writer has plotted on Fig. 2 the aeration period against the 5-day B.O.D. removed for sewages of widely differing strengths—that is, the weak North Side Chicago sewage, the comparatively strong Milwaukee sewage, and the very strong Chicago Packingtown sewage. Both the Chicago North Side and the Milwaukee plants were loaded to capacity and were operated so as to obtain the optimum results during the years included in the study. The Chicago Packingtown activated sludge experiments were conducted with the idea of obtaining optimum plant operation characteristics. In each case a high degree of purification was accomplished. The sludge is not re-aerated at Chicago and Milwaukee, and the data used from the Chicago Packingtown experiments cover only those in which the sludge was not re-aerated.

The aeration-period curve shown in Fig. 2 is plotted from the data given in Table 1(*a*). In Fig. 2 the point plotted for the Chicago North Side Plant is a practicable minimum of aeration period for a weak sewage. The aeration period plotted for Milwaukee (6.3 hr) is the average total aeration time, of which 5.44 hr constitutes the time in the aeration tanks proper; however, a material part of the difference is accounted for by the time of detention of the mixed liquor in the mixing channels. In the large scale experiments conducted by the Sanitary District of Chicago with Packingtown sewage in 1916 and 1917, a period of 9 hr was found to be a practicable minimum aeration time without re-aeration of the sludge.

TABLE 1.—CHARACTERISTICS OF "COMPLETE TREATMENT" OF SEWAGES OF DIFFERENT STRENGTHS

Plant	Period	(*a*) AERATION PERIODS REQUIRED					(*b*) OPTIMUM PERCENTAGES OF RETURN SLUDGE		
		Five-Day Bio-Chemical Oxygen Demand				Aeration period, in hours	Return sludge (percentage of incoming sewage)	Solids in return sludge (percentage)	Volatile matter in sludge solids (percentage)
		Raw sewage, in parts per million	Effluent, in parts per million	Plant removal, in parts per million	Plant removal (percentages)				
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)

The second important determination to be made in arriving at the aeration tank capacity is the percentage of return activated sludge. In the foregoing discussion of minimum aeration periods and, particularly in arriving at the aeration period curve shown in Fig. 2, it was assumed that the optimum percentage of sludge was being returned. The return of a large percentage of biologically active sludge will provide a quick coagulation adsorption of the impurities in the sewage, the time being inversely proportional to the percentage of sludge. However, after the initial coagulation adsorption has taken place, the larger percentages of return sludge seem to "rob" the sewage as the further oxygenation proceeds. Too small a percentage of return sludge (that is, less than that required to maintain biological activity) will require re-aeration of the sludge.

Without re-aeration of the sludge it appears, therefore, that the theoretical optimum percentage of return sludge is that percentage which will permit the required purification in a minimum of time and, at the same time, maintain an equilibrium of biological activity in the sludge. In general, the minimum percentage of biologically active return sludge will mean the minimum time for "complete" purification of the sewage. On the other hand, if this percentage of return sludge drops too low, the sewage will not remain biologically active.

As was the case with the aeration period and in the absence of experiments with the particular sewage, the best guide as to the optimum percentage of return sludge is the experience of plant operators, or of experimentation in plants where the percentage giving the best results has been determined.

As would be expected from theoretical considerations, the optimum percentage of return sludge found in the practical operation of activated sludge plants varies with the strength of the sewage in much the same manner as the aeration period. The optimum percentage of return sludge has been plotted against the 5-day B.O.D. removed for the same three sewages of widely differing strengths for which the aeration periods were plotted against 5-day B.O.D. removed. The data are such that the two curves may be plotted as an identical curve, as has been done in Fig. 2. The curve showing percentage of return sludge, in Fig. 2, is plotted from data in Table 1(*b*).

Although the curve for percentage of return sludge, shown in Fig. 2, does not take into consideration the percentage of solids in the activated return sludge, the determination of the optimum percentage of return sludge is usually related to the parts per million of solids maintained in the mixed sewage and activated sludge liquor.

In referring to the operation of the North Side Plant, in Chicago, treating a weak sewage with a 5-day B.O.D. of 116 ppm, Langdon Pearse, M. Am. Soc. C. E., states that it has been found practical to operate the plant with a smaller proportion of solids in the mixed liquor than the 3 000 ppm formerly assumed, and that by operating with approximately 2 000 ppm more flexibility is secured, with opportunity to store the increase of solids produced by storm flows. Mr. Pearse also found that some saving in air resulted and that it was practicable to cut the percentage of return sludge in volume, below 20.[6]

At the Milwaukee Plant with a sewage having a 5-day B.O.D. of 270 ppm, D. W. Townsend, M. Am. Soc. C. E., reports that it has been the custom in operating this plant to maintain a mixed liquor suspended solids content of approximately 3 000 ppm (0.3 of 1%), this solids content within reasonable working limits having been found to be about optimum for the general conditions encountered.[7]

The percentage of volatile matter in the sludge also affects the characteristics of the activated return sludge at least in so far as the rate of absorption of oxygen by the sludge is concerned.[4] However, few data are available to the writer as to how this affects the optimum percentage of return sludge.

The foregoing comments have been confined to the minimum practicable aeration period and optimum sludge return required for substantially complete treatment, as differentiated from partial treatment, and to the minimum time and optimum sludge return required without re-aeration of the sludge. Partial treatment and re-aeration of the sludge "go hand in hand." Re-aeration or re-activation of the sludge is required when the aeration period of the mixed liquor is insufficient to maintain either the biological activity or the oxygen requirements of the sludge, or both. With partial treatment, however, the demands on the sludge are so much greater and the required aeration period so much smaller that re-aeration of the sludge is required. Re-aeration is also required with either complete or partial treatment if the aeration period is kept at a minimum and the percentage of return sludge is too small, re-aeration being required because of the relatively heavy demands made on the sludge.

---

[6] "Comparison of Original Design Basis for North Side Treatment Works with Present Accepted Practice," by Langdon Pearse, Report to Public Works Administration, Board of Review, February 19, 1934.

[7] "Five Years Operation of Milwaukee Treatment Plant," by Darwin W. Townsend, *Proceedings*, Am. Soc. of Municipal Improvements, Vol. 39 (1933–1934), p. 189.

Even with complete treatment of the sewage, re-aeration of the sludge may be economical in many cases, particularly in the case of very strong sewages or industrial wastes.

The Chicago Packingtown sewage required 9 hr of aeration without re-aeration of the sludge. With re-aeration the average aeration period in the mixed liquor tanks was 5.3 hr with 3.8 hr aeration in the re-aeration tanks, the weighted average being equivalent to a 6.6-hr period as compared to the 9-hr period without re-aeration. The settling period however had to be increased from 1.3 hr without re-aeration to 1.7 hr with re-aeration. The re-aeration experiments indicated a net saving of 20% of tank volume (aeration tanks and settling tanks).

Evidence as to the economy in tank volume required in the treatment of sewage of average strength, because of re-aeration of the sludge, is not so clear. Unless it is possible to conduct large-scale experiments with the particular sewage being studied, the safe procedure is to design aeration tanks on the basis of the minimum volume required without re-aeration, in line with the curve shown in Fig. 2, but to provide sufficient flexibility in the number of aeration tanks or channels such that varying periods of re-aeration may be tried. Return sludge connections can usually be provided so as to use several of the channels as re-aeration channels at a relatively small additional cost.

DEPTH OF TANK

The use of a depth of 15 ft or, in some cases, a few inches less, for aeration tanks is almost universal in the large activated sludge plants in the United States. A number of diffused air plants in Great Britain use depths from 5 ft to 10 ft; however, the recently built and comparatively large plant at Manchester (16 mgd) uses a 15-ft depth. The plants at Houston have a depth over the diffuser plates of 9.75 ft. There are also a number of smaller plants in the United States using diffuser tubes at relatively shallow depths (5 ft, and less), but with tanks as deep as 15 ft.

In England the use of depths shallower than 10 ft can be largely attributed to the fact that many of the activated sludge plants were converted from existing works of other types of treatment where the existing tanks were of the shallower depths. Where the existing tanks were deeper, as at Worcester, England (17 to 18 ft), and at Reading, England (23.5 ft), the remodeled aeration tanks are of the same depth.

The prevalence of the 15-ft depth in the United States can be attributed largely to experience at Milwaukee and Chicago, where large-scale experiments were conducted with aeration tanks 10 ft deep, and 15 ft deep, run in parallel. The 15-ft depth was adopted at both Milwaukee and Chicago for the large activated sludge plants. At Milwaukee, the tests of the tanks 10 ft and 15 ft deep were discussed by the late Harrison P. Eddy, Past-President, Am. Soc. C. E., as follows:[8]

"The comparative efficiency of treatment in tanks 10 and 15 ft. in depth, was made the subject of careful and prolonged study at the Milwaukee Testing Station. Tests carried out with the greatest care, under the personal direction of William R. Copeland, Affiliate, Am. Soc. C. E., Chief Chemist, showed that, taking all the facts into consideration, it appeared that, for the same quantity of free air per gallon of sewage treated, there was little difference in the work accomplished by the 10-ft and the 15-ft tanks. The 15-ft tanks have produced an effluent of somewhat greater stability, whereas the 10-ft tanks have accomplished a slightly greater reduction in suspended matter and bacteria. If one depth of tank has an advantage over the other in purification efficiency, it seems to be the 15-ft. depth.

"An important consideration in the selection of depth of tank is the power required for compressing the air sufficiently to overcome the hydrostatic pressure of the several depths of sewage under consideration. In the cases of the 10 and 15-ft. depths, the latter would require 50% more power than the former, disregarding the effect of friction in pipe lines and porous plates. This saving will generally be offset, partly at least, by the increased cost of the larger area of tanks of the lesser depth. At Milwaukee, this is important because of the cost of the bulkhead, the sheet steel enclosure, and the pile foundation. Another important factor there is the limited area available for the treatment plant, as it is felt that additional area could not be devoted to this purpose, on account of the requirements for harbor development."

At Chicago, the sewage treatment works on the Des Plaines River were designed for experimental purposes with three aeration tanks of a depth of 10 ft and one of a depth of 15 ft. The results of the experiments as between the two depths, using the same volume of air per gallon of sewage, were summed up by Mr. S. L. Tolman, of the Sanitary District of Chicago, as follows:[9] "The operating data do not indicate any great difference in purification between these two depths."

Aside from the economy of construction cost of deep tanks over shallow tanks, another consideration is as to whether or not any appreciable oxygenation is accomplished by the air bubbles as they rise through the greater depth of liquor in the deeper tanks. As indicated by the Milwaukee and Chicago experiments this additional oxygenation in the deeper tanks is not material. This is probably due to two reasons: First, the bubbles rising through the liquid are enveloped in a surface tension film, including some colloidal matter (which film interferes with the passage of oxygen into the liquid at least until the bubble breaks the surface of the liquid[10]); and, second, the oxygen requirement of the sewage amounts to only a small percentage (not more than 10) of the oxygen in the air required for mixing and for maintaining aerobic conditions.

In a series of experiments conducted by the writer in 1925, nitrogen and air (also oxygen and carbon dioxide) were used in parallel for agitation of the mixed liquor, the raw sewage, the percentage and quality of activated sludge, the volume of gas, the aeration period, the depth of liquor, and the clarification period being identical for each gas. The air and the inert gas—nitrogen—gave practically the same results as may be judged from Table 2, which gives the results of the experiments.[11] The results of these experiments indicate that a large part of the oxygenation occurs as the bubbles break the surface of the mixed liquor.

TABLE 2.—COMPARISON OF NITROGEN AND AIR BUBBLE AGITATION

Description	FIVE-DAY BIO-CHEMICAL OXYGEN DEMAND IN PARTS PER MILLION		
	Medium strength sewage, Run No. 5	Strong sewage, Run No. 8	Average, Runs Nos. 1 to 8
Raw sewage	180	600	365
Effluent, using air agitation	16	40	24
Effluent, using nitrogen agitation	20	36	24

The foregoing considerations, particularly the results of the experiments at Milwaukee and Chicago, indicate that within practicable limits the economic depth of tank can be determined by balancing the greater cost of compressing air for the deeper tank against the lesser fixed charges for the aeration tanks of the greater depth. This problem may be readily analyzed by plotting the various costs against the corresponding depths.

The economic limit of depth is probably 15 ft to 16 ft, except in very extreme cases where the cost of site or of foundations (or of both) is very high. At Milwaukee, for example, where a 15-ft depth was used, the aeration tanks were built on "made" land and required bearing piles to support them. A number of British plants operate quite economically with depths of tank from 5 ft to 10 ft. Factors that would tend to increase the depth are, as follows: (*a*) Comparatively weak sewage requiring a small amount of air; (*b*) cheap power; (*c*) high construction costs; and (*d*) costly land for site. The City of Chicago is a typical example of a case in which these factors prevail. As a corollary, factors that would tend to decrease the depth are, as follows: (1) Comparatively strong sewage; (2) costly power; (3) low construction costs; and (4) inexpensive land.

In an attempt to gain the advantages of both the deep tank and the shallow tank a number of plants have been built in which the air diffusers, usually diffusion tubes, were placed above the mid-depth point in the tank, in some cases quite near the surface. In an aeration tank of this type it is essential that sufficient motion be imparted to the liquor to mix the sludge with the sewage and to prevent deposition of solids, as well as to maintain aerobic conditions in the mixed liquor.

---

[11] For a description of the experiments and analyses of oxygen consumed, dissolved oxygen, free ammonia, nitrates, and nitrites, as well as data covering other runs, see *Proceedings*, Texas Section, Am. Soc. C. E., Fall Meeting, 1925, pp. 13–36.

WIDTH OF TANK

Until quite recently, the ratio of width to depth of aeration tanks or channels has been maintained at less than 1.5, the British plants maintaining a ratio of approximately 1.0 and less. This was true of both the ridge and furrow and of the circulating or spiral-flow types of tanks. Inasmuch as the circulating or spiral-flow type of tank has largely superseded the ridge and furrow type due to the lesser air requirements of the circulating or spiral-flow type (as will be mentioned subsequently), this paper is confined to the latter type.

The new Cleveland Easterly Plant has a ratio of 1.8 (27-ft width by 15-ft water depth)[12] and the new Chicago Southwest Plant has a ratio of 2.1 (32.75-ft width by 15.5-ft water depth).[13]

The most careful observations available to the writer as to how wide the tank can be and still maintain good mixing and aeration are those made by the Sanitary District of Chicago at the North Side Plant. The observations were reported[6] as follows:

> "In the plant design, the batteries were divided up into 12 water-tight tanks, each of which was divided by a longitudinal baffle into 2 channels, 420 feet long and 16 ft. 1¾ inches average width. These channels were equipped with 2 rows of diffuser plates, running longitudinally. However, in the westerly tank, the dividing wall was omitted, giving a separate tank 33 feet 3½ inches average width. Experiments were carried out with channels 25 feet and 33 feet 3½ inches width to determine the efficiency of aeration with three longitudinal rows of diffuser plates.
>
> "Tests have shown that the effluent was equally as good with these widths as with the 16 ft. 1¾ inch width tank and no more air was required per gallon of sewage treated."

Based upon the operating data of the North Side Plant (0.4 cu ft of air per gal, 25% return sludge, and 4-hr aeration period), the use of air per foot of length for this particular channel may be assumed as between 4 and 5 cu ft per min. Inasmuch as the use of air at the North Side Chicago Plant, per gallon of mixed liquor per unit of time, is comparatively low, the foregoing observations indicate that a ratio of width to depth of as much as 2 is safe for a spiral-flow tank with diffusion plates along one side, unless the sewage is so weak as to require even less air than that at the Chicago North Side Plant.

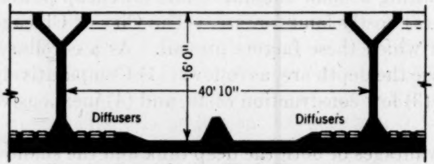

FIG. 3.—SAN ANTONIO (TEX.) EXPERIMENTAL AERATION TANK

At the treatment plant in San Antonio, Tex., the dividing wall was omitted between two aeration channels in order to observe the aeration in the wider channel. This channel has a ratio of width (40 ft 10 in.) to water depth over diffusion plates (14 ft 7.75 in.) of 2.8. The channel has a length of 150 ft, with three rows of diffuser plates longitudinally along each side of the channel and with an inverted V-shaped baffle, 3 ft high, longitudinally down the center of the channel. Fig. 3 shows a cross-section of the wide channel at San Antonio.

---

[12] *Engineering News-Record*, Vol. 107, p. 1035.

[13] From Contract Plans, Southwest Sewage Treatment Works, The Sanitary District of Chicago.

During 1934 the use of air per foot of length of the channel averaged 8.5 cu ft per min, or 4.25 cu ft per min per ft of length of diffusion plate system at each side of the channel (three longitudinal rows of plates in each diffusion plate system).

The liquor surface in the wide experimental channel at San Antonio reveals no well-defined dividing line along the center of the tank between the two spiral flows. The spiral flows creep from one side to the other of the center line of the tank; this creeping varies constantly and it is not known whether this is helpful in the mixing-aeration process, or whether it tends to create dead spots. H. A. Hunter, Assoc. M. Am. Soc. C. E., and W. S. Stanley, Chief Chemist and Superintendent, Sewage Treatment Plant, San Antonio, Tex., have made tests recently with the wide experimental tank as compared with the 20-ft tanks with diffuser plates on one side only. The effluent from the wide unit showed a smaller 5-day B.O.D. (3.3 ppm, as compared with 9.3 ppm); however, the flow through the wide tank had been throttled down so much that there was a considerably longer detention time in the wide unit than in the 20-ft unit used in the comparison. Further tests will be required to determine whether or not the results obtained in the experimental double unit are the equal of those obtained in the single units.

In a letter dated January 6, 1936, L. C. Whittemore, M. Am. Soc. C. E., states that an experimental aeration tank similar to the one at San Antonio, except that it is 68 ft wide, has just been placed in operation at the Chicago Calumet Plant. As at San Antonio, the diffuser plates are placed along both sides of the channel. He states further:

> "While it is, of course, too early to obtain any quantitative results or form any opinions as to the success of this arrangement, I saw the tank in operation the day sewage was put in it. The dividing line where the two currents from the sides of the tank was rather wavy and irregular, but there appeared to be good velocities maintained across the top of the tank toward the center."

Not only will the quantitative results at Calumet and more comparable results at San Antonio from the operation of the wide experimental units at these plants be instructive, but it will also be interesting to know the results obtained by placing the air diffusers along the center line of the tanks as compared with placing them on each side of the tank.

These experiments indicate the possibility of eliminating baffle-walls, or at least of cutting them down to small ridges midway between rows of plates, by properly placing the longitudinal rows of systems of plates. If the spiral-flow systems can be maintained satisfactorily by the energy of the air alone, the only limiting factors as to width would be a ratio of length to width sufficient to avoid short circuiting through the tank and a sufficient number of tanks to provide flexibility of operation.

Until such experimental works prove otherwise, existing data indicate a limit of the ratio of width to depth of approximately 2 to 1 for channels with diffusion plates on one side. The ratios should be modified to some extent depending upon the quantity of air necessary in the particular case.

QUANTITY OF AIR

The introduction of air in an air diffusion type of activated sludge plant serves two purposes: First, it mixes the sewage with the coagulating-adsorbing activated sludge and maintains the contact between the particles of activated sludge and the impurities in the sewage; and, second, it maintains aerobic conditions for the oxygenation of the mixed sewage-sludge liquor, or the sludge (or both), such that the sludge, or at least the return sludge, will be in a state of equilibrium in so far as its biological activity is concerned. The meeting of the second condition (the introduction of sufficient air to maintain the activity of the sludge) will more than satisfy the first condition as to the mixing of the sludge with the sewage, except possibly in the case of partial treatment plants requiring re-aeration of the sludge.

The air required to maintain aerobic conditions in the mixed liquor, or sludge (or both), for the required aeration period is approximately ten times that required to meet the bio-chemical oxygen demand of the sewage in an efficiently operated air-diffusion plant. Even then, a large part of the oxygen demand is no doubt met by oxygen from the atmosphere rather than from the diffused air introduced into the sewage, the atmospheric oxygenation taking place as air bubbles break the surface of the liquid. The quantity of air necessary to maintain sufficiently aerobic conditions for the oxygenation of the sewage or sludge (or both) is directly proportional, within a fairly narrow range, to the bio-chemical oxygen demand removed in an efficiently operated air-diffusion plant.

TABLE 3.—AIR REQUIRED PER PARTS PER MILLION OF FIVE-DAY BIO-CHEMICAL OXYGEN DEMAND REMOVED

Plant	Length of record, in months	FIVE-DAY BIO-CHEMICAL OXYGEN DEMAND, IN PARTS PER MILLION			QUANTITY OF AIR	
		Raw sewage	Plant effluent	Over-all plant removal	In cubic feet per gallon of sewage	In cubic feet per gallon per parts per million. 5-day B.O.D. removed
(1)	(2)	(3)	(4)	(5)	(6)	(7)
Chicago North Side (26 min preliminary sedimentation)	18	112	9	103	0.46	0.0045
Chicago North Side (preliminary sedimentation for 5.4 months only)	42	116	13	103	0.39	0.0038
Milwaukee (fine screens)	84	270	17	253	1.15	0.0045
San Antonio (41-min preliminary sedimentation)	61	196	15	181	0.97	0.0054
Indianapolis (fine screens)	96	287	35	252	1.13	0.0045
Chicago Packingtown	15 runs	752	32	720	3.06	0.0042

Table 3 shows the quantity of air required for a number of plants per gallon of sewage per part per million of bio-chemical oxygen demand removed. Table 3 also shows the nature of the preliminary treatment. Referring to Column (6), Table 3, the quantity of air used by the Milwaukee "ridge and furrow" type of aeration tanks (1.53 cu ft per gal) has been reduced by 25% (1.15) to obtain the comparison with the "spiral-flow" tanks used in the table. One-half the aeration tanks used in the Chicago Packingtown experiments were of the "ridge and furrow" type and air used in the experiments (3.5 cu ft per gal) has been reduced 12.5% to obtain (3.06) an approximation of the corresponding "spiral-flow" figure.

During the last twenty-four months of the Indianapolis record the plant was operated largely as a straight aeration plant rather than as an activated sludge plant. During this period (1933 and 1934) the plant reduction in parts per million of 5-day B.O.D. was from 256 to 94, making an over-all plant removal of 162 ppm, with a use of air of 0.64 cu ft per gal of sewage treated.

The quantity of free air required per part of bio-chemical oxygen demand removed over-all by a "complete treatment" air-diffusion plant seems to be largely unaffected by, and independent of, the aeration period, the percentage of return sludge, re-aeration of sludge, preliminary treatment by screens, or settling, or by depth of aeration tank. This assumes efficient plant operation and sufficient final clarification. The arrangement of the diffuser plates at the bottom of the aeration tanks, however, has a decided effect on the air required to maintain aerobic conditions in the mixed liquor. It has been demonstrated at a number of plants, particularly in experimental and full-scale units at Manchester, Chicago, and Indianapolis, that the "spiral-flow" type of tanks with the diffuser plates longitudinally along one side of the channels requires much less air to accomplish the same results than does the "ridge and furrow" type of aeration tank with the rows of diffuser plates cross-wise of the channels. The air saved by the "spiral-flow" type of tank over the "ridge and furrow" type approximates 25 per cent.[9] [14]

It is to be noted from Table 3 that the omission of preliminary treatment does not adversely affect the quantity of air required per part per million of 5-day B.O.D. removed by the plant as a whole. This is due no doubt to the fact that any solids removed by the preliminary treatment would settle out in any case in the final clarifiers and to the further fact that those solids are of such a nature that they will absorb a negligible quantity only, of oxygen as they pass through the aeration tanks.

The fact that Table 3 shows such uniform results with respect to the quantity of air required per part per million of 5-day B.O.D. removed by the over-all plant, in spite of the fact that a large percentage (30 to 40% in some cases) of the 5-day B.O.D. had been removed in the preliminary settling tanks in some of the plants, is attributable to the fact that the ratio to 5-day B.O.D. of suspended solids (and 5-day B.O.D. associated with those solids) is approximately the same for each of the plants for which comparable data were available. It is questionable whether the air consumption per part per million of bio-chemical oxygen demand removed, indicated in Table 3, would hold good for a strong industrial waste with a relatively small volume of settleable solids.

It is desirable to remove the grit from the sewage so that it will not settle in the aeration tanks or require too great a quantity of air to keep it in circulation. It has also been considered advisable from the standpoint of sludge disposal to settle out a considerable part of the solids in the preliminary tanks so as to obtain the higher concentration of solids (approximately 5%, or more) obtainable in the preliminary tanks as compared with the concentration obtainable in the final clarifiers (1% ±). However, there is some question as to whether the over-all concentration of solids from both the preliminary and the final tanks is any greater with the use of preliminary settling tanks. In a report to the Board of Review, Public Works Administration, for the West-Southwest Plant, Mr. Pearse stated,[6] as follows, with reference to preliminary settling tanks:

---

[14] "Sewage Aeration by Diffused Air," by Frank C. Roe, *Sewage Works Journal*, Vol. V, No. 5 (September, 1933).

> "In the original design, a preliminary settling period of 30 minutes on 175 m.g.d. was thought advantageous to reduce the settling solids and cut the use of air, based on experience at Calumet. Operating results for 18 months have indicated, however, on the North Side Plant, that the preliminary tanks are not necessary from the sewage treatment standpoint, as there is practically no difference in the amount of air used. Further, there has been no need of their use as skimming tanks for floating material. However, in the dewatering of the sludge the mixture of some fresh sludge with the activated sludge appears to aid in obtaining a higher rate of solid cake per square foot from the vacuum filters."

From the data available, therefore, it seems safe in the design of aeration tanks for "complete treatment" plants (without paddle-wheels or other mechanical aids to aeration), treating sewage without any unusual trade wastes, to provide 0.005 cu ft of free air per gal of sewage (average flow) per ppm of 5-day B.O.D. to be removed from the raw sewage by the over-all plant. Sufficient flexibility should be provided in the number and capacity of air compressors to permit a reduction to 0.004 cu ft (or even lower) of free air, should the actual operation of the plant permit of this minimum usage of air.

Considered entirely as an agitation device, a modern air-diffusion type of plant has an efficiency from "wire to sewage" of between 60% and 70%, depending to some extent upon the size and type of air compressors used. In other words, the work done on the sewage after taking care of all motor, compressor, air-piping, and diffuser-plate losses, approximates 60% to 70% of the energy delivered to the motor in a modern plant. (See operating data for Chicago North Side Plant and San Antonio.) Although these efficiencies were computed for plants using electrical power, plants using turbine-driven compressors show approximately the same efficiencies for the corresponding operations.

However, the function of an aeration tank is not agitation, in itself, but the maintenance of contact between the activated sludge and the sewage, under aerobic conditions. One form of agitation with air diffusion may be much more effective than another form, as is shown by the improvement of the "spiral-flow" form of aeration over the "ridge and furrow" type. There is promise of further improvement by utilizing a combination of air-diffusion agitation with mechanical agitation, such as the combination being utilized by Karl Imhoff, M. Am. Soc. C. E., at the sewage treatment plant in Essen-Rellinghausen, Germany, in which a submerged paddle mechanism revolves on a horizontal shaft running the length of the aeration channel in a direction opposite to the motion imparted by the air-diffuser plates located longitudinally along the side of the channel as shown in Fig. 4. Dr. Imhoff reports that with diffused air from 0.8 to 1.12 cu ft per gal and 24 hp per mgd were needed, but that with paddles in operation 0.16 cu ft of air per gal and 8.4 hp per mgd were found to suffice.[15] Mr. F. W. Mohlman and Charles E. Wheeler, Jr., Assoc. M. Am. Soc. C. E., of the Sanitary District of Chicago, reported similar results obtained on large-scale experiments (1 500 000 gal per day) with combination air-diffusion and paddle-wheel agitation. They found that it would require 0.80 cu ft of air per gal, with air alone, and a 5-hr aeration period to produce an effluent comparable with that produced by the paddle-wheel plus air, with 0.20 cu ft of air per gal of sewage and a 5-hr period. The paddles required 6.7 hp and the air 6.4 hp, giving a total of 13.1 hp per million gallons. With air alone at 0.8 cu ft per gal, and a 5-hr period, the total requirement would be 26 hp per million gallons.[16]

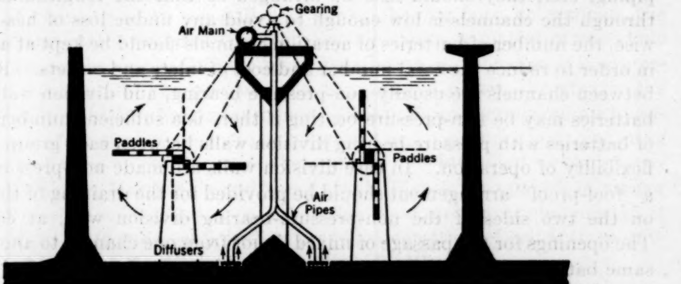

FIG. 4.—CROSS-SECTION OF AERATION TANK EQUIPPED WITH AIR DIFFUSERS AND PADDLE-WHEELS

AERATION TANK DETAILS

General Layout.—The laying out of the aeration tanks is entirely a matter of the most economical arrangement for the local conditions encountered. Plants of the air-diffusion type can be divided in general into two classes: (1) Those with an even number of channels in each aeration tank battery, arranged so that the inlet and outlet are at the same end of each tank battery of channels; and (2) those with an odd number of channels in each battery, arranged so that the inlet and outlet are at opposite ends of each battery. Conditions, any one of which may favor Class (2), are: (*a*) Incoming sewage main entering one side of plant site, with the effluent outfall out of plant site necessarily on opposite side; (*b*) re-aeration of return sludge, thus allowing return to the opposite side of the aeration tank battery through aeration channels; and (*c*) sludge return by pumping.

Conditions, any one of which may favor Class (1), are: (*d*) Plant size requiring "pipe gallery"; (*e*) incoming sewage main and effluent outfall entering and leaving the side of the plant site; and (*f*) sludge return by air lift.

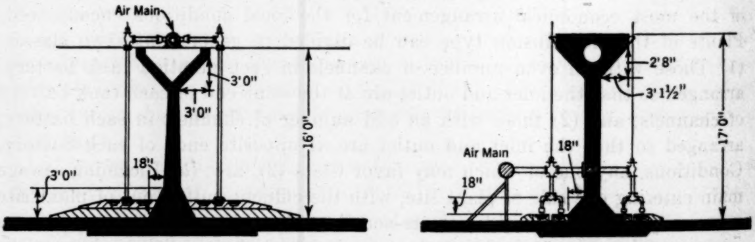
[15] "The Activated Sludge Process," by A. J. Martin, Macdonald and Evans, Lond., 1927, p. 252.

[16] "Activated Sludge Experiments at the Calumet Sewage Treatment Works," by F. W. Mohlman and C. E. Wheeler, Jr., Assoc. M. Am. Soc. C. E., *Sewage Works Journal*, Vol. II, No. 4 (October, 1930)

The aeration tanks should be divided into a sufficient number of batteries with pressure-bearing division walls between batteries to provide flexibility of operation and also to provide for the repair of diffuser plates, plate containers, piping, etc.; they should also be arranged so that the longitudinal velocity through the channels is low enough to avoid any undue loss of head. Otherwise, the number of batteries of aeration channels should be kept at a minimum in order to reduce the total number and cost of inlets and outlets. Baffle-walls between channels are usually non-pressure bearing, and division walls between batteries may be non-pressure bearing if there is a sufficient number of groups of batteries with pressure-bearing division walls between each group to provide flexibility of operation. In case division walls are made non-pressure bearing, a "fool-proof" arrangement should be provided for the draining of the batteries on the two sides of the non-pressure-bearing division wall, at equal rates. The openings for the passage of mixed liquor from one channel to another in the same battery should be large enough to avoid any appreciable head losses and should be at the bottom of the baffle-wall. The openings between channels in the new Southwest Sewage Treatment Works, at Chicago, are 10 ft high by 8 ft wide.

As previously stated, provision for reserving a part of the channels as sludge re-activation tanks can usually be made at a relatively small additional cost. This seems advisable in the case of strong sewages particularly in the absence of experimental plant data with the particular sewage to be treated. Aeration channels for mixing the return sludge with the sewage, influent channels into the different batteries, and effluent channels from the different batteries can often be made of substantially the same dimensions as the channels in the aeration tank batteries proper, usually at some saving in over-all plant cost and at no sacrifice in operating costs.

Section of Channels.—The capacity of tanks and the depth and width of channels have already been discussed. Since the development of the fact



(*a*) DALLAS, TEXAS, PLANT (DESIGN) (*b*) CHICAGO SOUTHWEST PLANT

FIG. 5.—TYPICAL WALL SECTION SHOWING AIR PIPING AND DEFLECTORS

that the spiral-flow type of tank or channel, with the diffusion plates along one side of the channel, saves considerable air over the ridge and furrow type of aeration channel with plates across the channel (see heading "Quantity of Air"), practically all new plants have utilized the spiral-flow type of tank. The main object to be attained in this type is to maintain the spiral flow with a minimum of dead spaces, eddying, and friction losses. As a result of considerable experimentation corner deflectors at an angle of approximately 45° with the vertical are generally used. Fig. 5 shows two typical examples of channel cross-sections with the dimensions of corner deflectors.

Diffuser Plates.—Tank dimensions, aeration period, percentage of return sludge, and quantity of air per gallon of sewage having been determined, the area of diffuser plates required is, within certain limits, a matter of economic balance between the cost of diffuser-plate installation and the cost of compressing air to take care of the pressure loss through the plates, the greater the number of plates the less the pressure loss. The practicable range of air quantity per square foot of plate seems to lie between 1 and 4 cu ft per min, operating difficulties being encountered outside these limits. As indicated by the experience of the Chicago North Side and San Antonio Plants, 4 to 6 cu ft of air per min per ft of channel will induce a circulatory flow motion in channels 15 ft deep and 33 to 40 ft wide, sufficient to prevent deposition of solids from grit-free mixed liquor (see heading "Aeration Tank Widths").

The size of air bubbles is important. Mr. Lockett reached the conclusion, as a result of some experiments with Manchester sewage, that diffused air is approximately three times as effective as air applied in the form of large bubbles such as obtain with plain tube aeration.[17] It was thought formerly that the size of bubble from diffuser plates varied inversely as the permeability of the diffuser plate, permeability being defined as that quantity of dry free air, in cubic feet per minute, which will pass through 1 sq ft of dry plate at 70° F, and 30 in. of mercury absolute, under a pressure equivalent to 2 in. of water. For this reason plates of a relatively low permeability (10 to 25) and with relatively high frictional resistance (8 to 12 in. of water with 2 cu ft per min per sq ft of wet plate) were used. It has been found, however, that permeabilities of between 30 and 40 and even as much as 50 are satisfactory, and that there is little difference in the size of bubbles diffused from plates of 15 permeability and those diffused from plates of 60 permeability. Mr. Arnold J. Beck, of the Sanitary District of Chicago, has found that the average bubble diameter diffused from forty permeability plates under normal operating conditions is 0.0813 in., having a volume of 0.00028 cu in.[18] The plates of the higher permeability not only have lower frictional resistances (4± in. of water), but also do not clog as readily as the plates of lower permeability.

Plate dimensions have been standardized at 12 in. by 12 in., with thicknesses from 1 to 1.5 in.; however, it is understood that plates 18 in. square are being considered for large installations.

The diffuser plates may be set in concrete or in metal plate containers, or they may be set directly into concrete air channels in the bottom of the aeration tanks. Plate containers holding as many as eight to ten individual plates are in common use. Whether plate containers are used, or whether the plates are set directly into channels formed at the bottom of the tanks, the bottoms of the aeration tanks should be poured flat and the containers or concrete channels built up in the bottoms of the tanks. Plate containers are favored on large installations; however, with careful workmanship in the forming and pouring of concrete plate channels, plates may be satisfactorily set into the bottoms of the tanks without the aid of plate containers.

---

[17] "Activated Sludge Process: Aeration and Circulation," by William T. Lockett, *Proceedings*, Assoc. of Managers of Sewage Disposal Works, 1925, p. 94.

[18] Paper presented before the Eighth Annual Convention of the Central States Sewage Works Assoc., Urbana, Ill., October 25, 1935. (Not published.)

Plate containers have usually been of pre-cast concrete sometimes with non-rusting metal edges next to the plates, or with metal supports between the plates, or both. A cast-aluminum container, recently developed, is now being used. Cement grout is the generally accepted jointing material; however, the plates cannot be readily removed where a cement grout is used. The use of rubber gaskets and wedges with clamps for holding the plates in place offers possibilities in the direction of a jointing material which will allow easy removal of the plates. Rubber gaskets should be corrugated so as to obtain a good air seal which is not obtainable with a plain rubber gasket. A special rubber has been developed for use in sewage.

Diffusion tubes have been used on several smaller installations. These tubes have the advantages of being easy to remove and clean without draining the aeration tank and of utilizing the economy of deep tank construction and, at the same time, of being placed at relatively shallow depths, thereby making a saving in the cost of air compression. The disadvantages of diffuser tubes are the higher cost than the cost of plates for a given air capacity and the unevenness of air dispersion due to the fact that the air tends to escape through the top of the tube.

The air used in diffuser plates or tubes should be filtered so as to remove any foreign matter that would tend to clog the diffusers; air compressors, air piping, and plate containers should be of materials and construction such as not to permit oil, rust, or flaking from metal to get into the air stream.

Air Piping.—The main object to be attained in the design of air piping is a uniformity of air pressure over the entire aeration tank with due regard to economic balance between installation and compression costs. In general, this will mean over-sized pipe rather than the economic size of pipe computed strictly in accordance with the air-flow formula.[19] Losses in heads in valves are conveniently computed on the basis of the additional length of straight pipe to give an equivalent loss (see tables in compressed air handbooks). Although air-valves are almost universally placed on the feeder pipes to a group of diffuser plates, these valves should not be depended upon for close regulation of air pressure. Standard angle-valves are usually all that are required for feeder pipes to each plate container, or group of containers, although needle-valves have been found convenient in small plants.

In some large plants air mains are run longitudinally along the aeration channels 4 or 5 ft above the bottom of the channels, each main serving two channels with laterals through the baffle-walls or the division walls; generally, however, the mains are carried on top of the V-shaped baffle or division mains with each main serving two channels. The two methods are illustrated in Fig. 5. The question as to which system to use is largely a matter of cost in each particular case; however, the mains placed down into the channel have the disadvantage of creating eddies in the spiral flow of the liquor and of increasing the tank friction. In so far as possible the air piping should be designed and housed so as to conserve the heat in the air, inasmuch as the volume of the air delivered to the plates and the work done by it merely as a mixing agent is directly proportional to the absolute temperature of the air. Where the plate containers are poured in place on the bottom of the tanks and where the air channel beneath the plates is continuous and sufficiently large, the number of air-pipe laterals (down pipes) may be considerably reduced, or even eliminated, by making connections at each end of the air channel beneath the plates. The use of a continuous air channel also assists in the drainage of the air channels beneath the plates. Where a continuous channel is used the plates should be distributed uniformly along the channel with reference to permeability.

---

[19] For a comparison of various formulas see "Air-Pressure Losses in Piping of Activated-Sludge Plants," by Henry L. McMillan, M. Am. Soc. C. E., *Engineering News-Record*, Vol. 91, No. 5, August 2, 1923.

Piping may be of cast iron, galvanized iron, or steel, galvanized iron being preferred for small sizes (4 in., or less), cast iron for intermediate sizes (6 in. to 36 in.), and steel for larger sizes, although this is a matter of wide variation. Inasmuch as the air piping is subjected to differences in temperatures of as much as 200° F, ample expansion joints should be provided. In general, bell-and-spigot joints on cast-iron pipe and flexible couplings on steel pipe will provide for contraction and expansion.

Method of Returning Sludge.—The sludge should be returned uniformly from the clarifiers (that is, the same percentage should be returned) to each aeration tank battery. This may be obtained: (1) By mixing all the return sludge and raw sewage for the entire plant in a mixing channel before the mixed liquor goes into the aeration batteries; (2) by dividing the plant into a number of units which will accomplish the same result as under Method (1); or (3) by measuring or proportioning devices which will insure the correct ratios of sewage and sludge being drawn into each aeration battery from a common sewage-feed channel and a common return-sludge channel.

Many of the early activated sludge plants (Manchester, Worcester, Houston, and others) have air-lifts for returning sludge; however, most of the large plants built in the United States since the Houston plant have been equipped with centrifugal pumps for returning sludge. The personnel at the Chicago Sanitary District has obtained, by experimentation, a sufficiently efficient air-lift to meet its particular needs at the new Southwest Sewage Treatment Works and has incorporated sludge return air-lifts in the plans for the Southwest Treatment Plant. Again, this is a matter of cost, although the air-lifts no doubt accomplish some aeration. Although pumps have some advantage over air-lifts in the matter of efficiency, in a large plant, the cost of, and the head losses in, the piping or channels (or both), used in getting the sludge from the clarifiers to the pumps and back to the aeration tanks, may more than offset the efficiency advantage of the pumps. In a large plant the air-lifts may be placed between one or more aeration tank batteries and the clarifiers serving them so as to obtain a maximum of simplicity in sludge-return piping.

Measuring Devices.—However small or large the plant, the aeration tanks and appurtenances should be equipped with devices for measuring sewage flow, power, air, return and excess sludge, temperatures of air, sewage, and atmosphere, and air pressures. If the plant consists of more than one aeration tank battery, either measuring or proportioning devices should be provided for assuring an equable flow of sewage, return sludge, and air to each aeration tank. Measuring devices of the Venturi tube type have proved satisfactory for sewage, return sludge, and air. In many plants the return sludge is mixed with the raw sewage before subdividing the flow of mixed liquor into the individual aeration tank batteries, adjustable weirs being used either at the inlet or at the outlet of the aeration tanks to secure an equal distribution to the different tanks. Air-valves alone are usually depended upon to secure an even distribution of air.

CONCLUSIONS

The curve shown as Fig. 2 is offered as an attempt to arrive at a practical guide to be used in approximating the detention period and percentage of return sludge to be provided for in the design of aeration tanks. It is questionable whether the curve is applicable to activated sludge plants treating certain trade wastes with unusually high ratios of bio-chemical oxygen demand to suspended solids. The plant-operating data from which the curve was plotted indicate that the detention period and percentage of return sludge and, consequently, the capacity of the aeration tanks, should be largely proportional to the strength of the sewage to be treated. In the writer's opinion, this is in accordance with the theoretical considerations involved.

Once the capacity of the aeration tanks is determined, details of the tank design are largely a matter of the economic balancing of costs. Improvements in the design of aeration-tank accessories are being made continuously.

ACKNOWLEDGMENTS

Information to support the views offered in this paper was secured from various sources, for the most part, as cited by footnote references. However, special acknowledgment is due to L. C. Whittemore, M. Am. Soc. C. E., for data pertaining to the Chicago North Side Plant; Darwin W. Townsend, M. Am. Soc. C. E., for data observed at the Milwaukee Plant; and C. K. Calvert, Affiliate, Am. Soc. C. E., for data relative to the Sewage Treatment Plant at Indianapolis.

DISCUSSION

Norval E. Anderson,[20] M. Am. Soc. C. E. (by letter).—In his comprehensive presentation of the factors entering into the design of aeration tanks, the author notes the almost general acceptance of the 15-ft depth in the United States, but apparently is not convinced that this standardization is justified. The apparent inadequacy of data on the optimum depth of aeration tanks prompted the writer to undertake a rather extensive theoretical investigation of the question, the results of which were presented[21] in 1934. This theoretical investigation did not lead to any conclusive results. However, it is believed that a logical approach to the question was made and that some of the possibilities and limitations were evaluated approximately.

The method of approach was to set up three different theories of the possible relation between depth and air requirements, derive the necessary equations for each, assume basic operating conditions, and compute for each theory the relative air requirements for various depths.

The linear velocity theory is based on the assumption that for a given sewage, a certain minimum quantity of air (considerably less than present use) is required for oxidation, but that additional air is required to maintain a certain degree of agitation or velocity of circulation, and that this degree of agitation may be measured by the linear velocity of circulation. From this it would follow that the air required (within practical limits) is determined by the power that must be imparted to the sewage, in order to maintain a given velocity of circulation of the liquid in the tank. It can be demonstrated that on this basis the power-depth relation is a simple hyperbolic function of the form: $\text{Power per unit volume} = \frac{1}{\text{depth}}$.

The relative velocity theory, like the linear velocity theory, is based on the assumption that for a given sewage a certain minimum quantity of air is required for oxidation, but that additional air is required to maintain a certain degree of agitation or velocity of circulation. However, for this relative velocity theory, it is assumed that the necessary degree of agitation is measured by a velocity related to the tank depth. The relative velocity is assumed to be that which would give an equivalent hydraulic effect (the relation used in comparing hydraulic models), which is $V = \sqrt{\text{depth}}\, V'$. It can be demonstrated that to maintain this relative velocity, the power per unit of volume, neglecting distribution losses, remains the same for any depth.

In the contact theory the effectiveness of aeration may be measured by the area and time of contact between the air and the liquid in the tank. Furthermore, to obtain the same results from tanks of various depths, the unit of air contact area per unit of liquid volume must be kept the same. The air contact would be both that with the air bubbles and that with the atmosphere.

[21] "The Economical Depth of Aeration Tanks of the Diffused Air Type for the Activated Sludge Process of Sewage Treatment," by Norval E. Anderson. (Thesis presented in partial fulfillment of the requirements for the Professional Degree of Civil Engineer in the Graduate School of the Univ. of Illinois, 1934.)

In order to compute results in accordance with this contact theory, a number of approximations and assumptions (many of them controversial) must be made. These assumptions, all of which have some experimental basis, are as follows:

(1) Air forms bubbles of approximately the same size (about 0.01 ft) soon after emerging from the diffusers; and they remain this average size throughout the length of travel.

(2) The upward velocity of air bubbles relative to the liquid is approximately 0.8 ft per sec;

(3) The average velocity of circulation of the liquid in the path of travel in a 15-ft tank using 0.40 cu ft of air per gal of sewage, is approximately 1.7 ft per sec;

(4) The length of travel of air bubbles in the tank is approximately 1.2 times the depth of water over the diffusers; and,

(5) The atmospheric surfaces and the bubble surfaces are equally effective per unit of area, except as modified by Henry's law.

Assumption (5), although apparently contrary to the results of Mr. Freese's experiments, is supported by the experimental results of A. S. Parsons and H. Wilson[22]; G. J. Fowler and S. N. Chatterjee[23]; W. E. Adeney and H. G. Becker[24]; and H. G. Becker.[25] W. K. Lewis and W. G. Whitman[25] conclude that "gas bubbles * * * are particularly adapted to the absorption of the less soluble gases."

Operating data assumed as a basis for computing the comparisons are taken from approximate actual conditions at the North Side Treatment Works of The Sanitary District of Chicago, Chicago, Ill., representing rather efficient operation with a weak sewage. These assumptions are: Aeration tanks are of the circulating or spiral flow type; the water depth of the tank over the diffusers is 15 ft; the air used was 0.40 cu ft of free air per gal of sewage; the air distribution pressure loss was 1.30 lb per sq in.; the blower efficiency was 65% over-all; the average aeration period of sewage was 5 hr; and the average sludge return was 20% of raw sewage. It is further assumed that for any depth of tank the width may be approximately twice the depth.

The comparative air and power requirements for tanks of various depths, computed in accordance with the foregoing theories and assumptions, are given in Table 4.

The almost total lack of direct experimental evidence makes any discussion of the relative merits of the different theories unconvincing. However, there is some indirect evidence which seems pertinent.

[24] "The Determination of the Rate of Solution of Atmospheric Nitrogen and Oxygen by Water," by W. E. Adeney and H. G. Becker, *Philosophical Magazine*, Series 6, April, 1920, Vol. 39, pp. 385–404.

[25] Absorption Symposium: "Principles of Gas Absorption," by W. K. Lewis and W. G. Whitman; "Mechanism of Absorption of Moderately Soluble Gases in Water," by H. G. Becker; and "Effect of Gas Velocity and Temperature on Rate of Absorption," by R. T. Haslam, R. L. Hershey, and R. H. Keen, *Industrial and Engineering Chemistry*, December, 1924, Vol. 16, No. 12.

Consideration of the factors involved in the computations for the contact theory indicate that if they were applied to aeration tanks of the ridge and furrow type, the results would show a greater air economy than for tanks of the circulating type, since the bubbles would be retained longer in the tank, due to the absence of the circulating velocity, whereas the surface contact would be the same. Operating experience has demonstrated the opposite. This points to the predominating influence of mixing or stirring the liquid.

The importance of stirring is emphasized in the Absorption Symposium,[25] previously cited, in which Messrs. Lewis and Whitman call attention to the remarkable agreement between the results of Becker and others as to the effect of stirring on the rate of absorption, and find that this rate increases as the 0.8 power of the rate of stirring. Further evidence to the same effect is offered by the experiments of The Sanitary District of Chicago and by Karl Imhoff, M. Am. Soc. C. E., at Essen-Rellinghausen, Germany, with submerged paddle-wheels to maintain circulation, thereby reducing the quantity of diffused air required.

TABLE 4.—COMPARATIVE AIR AND POWER REQUIREMENTS

Water depth over diffusers, in feet	FREE AIR REQUIRED, IN CUBIC FEET PER GALLON			BRAKE HORSE-POWER PER MILLION GALLONS PER DAY		
	Linear velocity theory	Relative velocity theory	Contact theory	Linear velocity theory	Relative velocity theory	Contact theory
5	3.26	1.09	0.63	48.8	16.3	9.5
10	0.87	0.58	0.48	20.4	13.6	11.2
15	0.40	0.40	0.40	12.4	12.4	12.4
20	0.23	0.31	0.36	8.9	11.9	13.6
25	0.15	0.26	0.32	6.9	11.5	14.6
30	0.11	0.22	0.30	5.7	11.4	15.6

Of the two velocity theories, the relative velocity theory seems much the more reasonable since it gives a measure of the stirring in relation to the mass of the liquid. Furthermore, any such pronounced change in air requirements with change in depth, as indicated by the linear velocity theory, would probably have been noticed before, even with the limited opportunity for comparison.

Again referring to the Absorption Symposium,[25] it is found that the rate of absorption is dependent upon the area of interface in relation to the volume of liquid, as well as upon the rate of stirring. Since the relative importance of these factors in an aeration tank is not known, it is possible that the true power-depth relation lies between the contact theory and the relative velocity theory, although the latter probably predominates, especially for a weak sewage.

In view of the foregoing comment it appears that there probably is not much difference in power requirements per million gallons per day of sewage treated over a practical range of depths, and that more consideration may be given to relative construction costs as affected by any particular site. If the foregoing is accepted, it would modify the author's conclusions regarding depth (see text following Table 2) in two respects: (1) It is not certain that there is an increase in the cost of power with increased depth; and (2) the economical depth may be considerably more than 15 ft under less than extreme conditions as applied to costly sites or foundations.

Weston Gavett,[26] Assoc. M. Am. Soc. C. E. (by letter).—The larger sewage treatment works generally have better facilities for research and investigation of plant problems than the smaller works although all experience the same difficulties. No doubt a large fund of valuable information has been accumulated at various plants that has not been published. Mr. Freese has done a useful service in presenting and interpreting data from some of the larger works.

Table 1 and Fig. 2 are interesting in indicating the optimum aeration time and percentage of return sludge for sewages of various strength as expressed by bio-chemical oxygen demand (B.O.D.). The direct relationship between optimum aeration time and percentage of sludge seemed surprising at first glance. The fact that 5-hr aeration time required 20% return sludge whereas 8-hr aeration time is definitely coupled with 50% sludge, appeared to contradict the opinion of Mr. F. W. Harris and his collaborators[27] that percentage sludge times aeration time is a constant for any given sewage. When it is realized that the values in Fig. 2 are minima for complete treatment without re-aeration of sludge, the data are not inconsistent with Harris' results. The curves in Fig. 2 may be expressed approximately in the formulas:

$$T = 4.5 + 0.00625\ (\text{B.O.D.}) \qquad (1a)$$

$$S = 15 + 0.0625\ (\text{B.O.D.}) \qquad (1b)$$

$$S = 10\,T - 30 \qquad (1c)$$

and,

$$T = 3 + \frac{S}{10} \qquad (1d)$$

in which T = aeration time, in hours; S = percentage return sludge; and, B.O.D. = 5-day bio-chemical oxygen demand, in parts per million. Mr. Harris expressed the relationship between time and percentage of sludge as:

$$S\,T = C \qquad (2)$$

in which C is a factor for a given strength of sewage. The percentage of sludge used by Mr. Harris is the percentage in the mixed liquor rather than that in return sludge as used in Fig. 2.

Assuming that C is a function of the B.O.D., the values in Fig. 2 indicate that $S\,T = 0.7$ B.O.D. to 0.8 B.O.D., except for low values of bio-chemical oxygen demand. For a sewage with a bio-chemical oxygen demand of, say, 400 ppm, Fig. 2 indicates the minimum time of aeration as 7.0 hr and the minimum percentage of returned sludge as 40. If, however, $S\,T = 0.7$ B.O.D., with the same 400 B.O.D. sewage, good results should be obtained with 10 hr aeration and 28% returned sludge or 6 hr aeration time and 47% sludge, although the need of re-aeration of sludge would be expected with an aeration time of less than 7 hr as shown by Fig. 2. A more general and useful expression would be obtained if the percentage of sludge were expressed (as done by Mr. Harris) as the percentage of sludge in mixed liquor after 1 hr of settling, or better as parts per million of suspended solids in the aeration tank. As the author states (see heading, "Aeration Tank Capacity"), "the percentage of return sludge, shown in Fig. 2, does not take into consideration the percentage of solids in the activated return sludge * * *." In view of the considerable variation in the concentration of solids in return sludge carried at various plants, relationships based on percentage return may be misleading unless based on sludges of similar concentration.

---

[26] San. and Hydr. Engr., Clyde Potts, New York, N. Y.

[27] "The Activated Sludge Process," by A. J. Martin, Macdonald and Evans, 1927, p. 165.

Experience at five plants confirms the author's statement of the advantages of diffuser tubes. The writer questions the "unevenness of air dispersion due to the fact that the air tends to escape through the top of the tube" (see "Aeration Tank Details: Diffuser Plates"). A photograph of air diffusion from a tube which appeared in a trade publication showed most of the air escaping from the top of the tube, but the tube had little water over it. When a tube is submerged 6 ft in water, the effective pressure on the top of the tube equals 6 plus tube friction and on the bottom of the tube, 6 ft 3 in. plus tube friction. The difference is slight and should not cause great difference in air diffusion. The writer believes a further advantage of tubes is the efficient distribution of air through the tank contents. Experiments at Morristown, N. J., showed that with tubes 4 ft above the bottom in a 10-ft depth of sewage, best results were obtained when the tube was located away from the adjacent wall a distance equal to one-tenth the width of the tank. When near the wall much of the air appeared to escape along the wall without doing its share of useful work. When placed too far away from the wall the circulating velocity of the tank decreased. At the best location the air appeared to be well distributed through the sewage.

As with plates, a higher permeability was found advisable for tubes. At Mineola, N. Y., in 1928, and for Rockville Centre, N. Y., in 1929, tubes were specified with a permeability equivalent to a plate 1 ft sq with permeability of 14 to 16. Flushing by water was found useful in keeping tubes clean at Rockville Centre. Mr. Paul Molitor, Sr., cleaned tubes by a 40% nitric acid bath and heating at Chatham, N. Y.[28] Tubes at Bernardsville, N. J., were specified to pass 50 to 60 cu ft per min under 2-in. water pressure when dry, or approximately equivalent to 25 to 30 permeability for a 1-sq ft plate. At this plant only one-half the available aeration tanks are in use, so that tubes are changed once a year and allowed to rest every other year. No cleaning has been necessary since the plant was placed in operation in October, 1933. Perforated copper pipes installed at Morristown were replaced by diffuser tubes. The writer believes that the possibilities of perforated pipe have not been sufficiently investigated. When holes are perforated in the bottom of pipes which are placed above the bottom, the velocity of the rotating sewage has a sweeping effect that disperses the air bubbles effectively.

---

[28] *Proceedings*, New Jersey Sewage Works Assoc., 1932, p. 26.

S. W. Freese,[29] M. Am. Soc. C. E. (by letter).—The discussion by Mr. Anderson, giving possible theoretical bases of determining the economic depth of aeration tanks, is a long step toward providing a rational solution of this problem. The difficulty of choosing between the various possible theories or combination of theories emphasizes the desirability and need of parallel experiments with aeration tanks of different depths, such as 5, 10, 15, and 20 ft. The results of such experiments, taken together with the possible theories outlined in the discussion, should provide a rational basis for determining the depth of aeration tanks. In the meantime, the data available tend to limit the designer to a 15-ft depth of tank.

An experimental determination of the weight to be given to "linear velocity," "relative velocity," "contact," and any other factor or factors affecting aeration, would be useful not only in determining depth, but in determining whether the air-diffusion type, the "mechanical" type, or a combination of the two, is the most economical method of aeration.

Mr. Gavett calls attention to the fact that Mr. F. W. Harris and his collaborators found[3, 27] that "percentage sludge times aeration time is a constant for any given sewage." This is largely true during the first or "coagulation-adsorption" stage rather than in the second or "oxygenation" stage of the aeration period for complete treatment plants. In the writer's opinion, the findings of Messrs. Grant, Hurwitz, and Mohlman[4] complement those of Messrs. Harris, Cockburn, and Anderson[3, 27] in affording a complete picture of the two stages.

The formulas for aeration time and percentage of return sludge which Mr. Gavett has developed provide useful guides for the determination of the capacity of aeration tanks for complete treatment plants of the air-diffusion type. As to the percentage of solids in the return sludge, it is to be noted from Table 1 that the Chicago North Side return sludge contained 1.39% of solids and the Milwaukee sludge contained 1.19 per cent. It is not believed that the solids in the return sludge of a well-operated plant treating domestic sewage will vary greatly from these latter values.

AMERICAN SOCIETY OF CIVIL ENGINEERS
Founded November 5, 1852
TRANSACTIONS

Paper No. 2013

THE RELATION OF THE NATIONAL SOCIETY TO THE ENGINEERING PROFESSION

ADDRESS AT THE ANNUAL CONVENTION, SALT LAKE CITY, UTAH, JULY 20, 1938

BY HENRY EARLE RIGGS,[1] PRESIDENT, AM. SOC. C. E.

The long continued depression in the United States has created many grave and serious problems, not only for individuals and business firms and corporations but for social and professional organizations and groups. The profession of engineering has been greatly affected. From a peak of professional activity in 1930, with the highest scale of compensation for service that has ever prevailed, the profession plunged to the depth of depression in 1932 with many thousands of engineers out of work, and many apparently substantial and prosperous engineering firms out of business. In the years since then a great part of the work of the civil engineers has been in connection with Federal pump priming or relief work, some of it being major projects of large size and of fine character, but a large part of it being pure relief work of little professional interest and offering inadequate pay.

Any thorough investigation will compel admission of the fact that there is a great increase of engineering employment on government work, and an appalling lack of employment of engineers on privately financed corporation enterprises.

If a study of the profession were to be made to-day it would disclose the fact that large numbers of the older engineers, many of whom had believed that their investments assured a safe and comfortable old age, and several thousand younger ones who had purchased or built homes or made considerable investments on which obligations were outstanding, have had everything swept away and find themselves now wholly dependent on the continuance of steady employment.

There has been disillusionment and despair for many and there is doubt and uncertainty as to the future in the minds of many others. The student in the upper classes in college is asking whether engineering is a worth while pursuit. The engineering graduate who has found little or no engineering work in the last seven or eight years or who has been given no chance to assume any degree of professional responsibility has the same doubt.

---

[1] Honorary Prof., Civ. Eng., Univ. of Michigan, Ann Arbor, Mich.

The whole ugly picture of depression—of the great volume of "made work," much of it without proper engineering supervision and all of it with underpayment of professional men; of the great labor unrest and of the excessive activity of labor unions; of the distinctly domineering character of some of these unions; of the extensive entry of government into business in competition with private capital; and of the fear that undeniably is nation-wide, that stifles individual initiative, and prevents individual investment in new projects—all this constitutes a picture that compels analysis of conditions in the engineering profession. What must be done to keep up the morale and to help to eliminate the abuses which many engineers have experienced?

In large measure this Society and the other great engineering societies founded in later years are responsible for the splendid development of the profession of engineering and for its gradual but sure recognition as one of the great and learned professions. It is in only comparatively recent years that full understanding has come of the importance of engineering to the nation and of the need for engineers not only to design and build plants but to maintain and operate them and to administer the higher executive offices in transportation, utility service, and manufacturing as well as in municipal, state, and national service.

It is to the great engineering societies that the discouraged engineer naturally looks for help in his time of need. Can the Founder Societies be of service? Is the American Society of Civil Engineers so organized that it can take the place of leadership when leadership is so much needed?

Any discussion of the relationship of the profession of engineering to these conditions of to-day should be prefaced by a review of the growth and development of the American Society of Civil Engineers which is probably typical of that which has taken place in all the older engineering societies. Such a review is found in the Annual Address of Arthur S. Tuttle, Past-President, Am. Soc. C. E., in 1935.[2] There is no need to repeat the history given by him. The three years that have passed since then have justified many of his prophecies. They have also brought new problems which call for consideration some of which were indicated by Louis C. Hill, Past-President Am. Soc. C. E., in his Annual Address in 1937.[3]

FUNDAMENTAL ORGANIC CHANGES IN THE CONSTITUTION

This address is an attempt to supplement and expand the discussion of these problems in the light of present-day conditions and to point out why and how the fundamental organic changes in the Constitution of our Society were brought about.

During the eighty-six years of the Society's existence it has changed its organic form and adjusted itself to meet the developing needs of the profession. Starting as a local society in the largest city of the United States it passed a membership of 500 in its twenty-third year—1875. The need of those earlier times was for improved technical work and the Society was established with the major objectives of bringing together engineers of the highest professional standing, of developing a professional *esprit de corps*, of raising standards of ethics and the practice of engineering, and of building up American technical literature in all branches through the recording of the accomplishments and researches of its members. The excellence of its technical work and its high standards of membership drew to it many engineers resident outside of the City of New York so that it grew to a membership of 1 000 in 1887, to 2 000 in 1897, and 3 000 in 1904.

---

[2] *Transactions*, Am. Soc. C. E., Vol. 100 (1935), pp. 1407–1425.

[3] *Loc. cit.*, Vol. 102 (1937), pp. 1173–1177.

The Constitution adopted March 4, 1891, undoubtedly represented the opinion of the then membership as to the form of government desirable at that time. It provided for no zones and no districts. The Board of Direction consisted of four Vice-Presidents and eighteen Directors at large and all living Past-Presidents. The Year Book of 1894 shows twelve Past-Presidents as members of the Board, making a total of thirty-five members. Nine members of the Board constituted a quorum at the time of the annual meeting and annual convention and five at all other meetings of the Board.

The Constitution provided that nominations for all offices should be made by a nominating committee. In 1887 five districts were established for the purpose of selecting this nominating committee at the annual business meeting. In 1891 the committee was increased to seven, and seven districts were established. There were two general business meetings of the Society a year, at the annual meeting and the annual convention, besides monthly business meetings at New York, at which thirty members constituted a quorum. There were no local sections, no student chapters, no technical divisions, no technical or research committees, and only three standing committees of the Board, on Finance, Library, and Publications.

It is obvious that a Board of Direction with a membership of ten or more from the New York metropolitan area, with a quorum of nine at the annual meeting and annual convention and five at other meetings, all of which were held in New York City, was largely governed by the representatives of the New York area, especially as non-resident Board members did not receive mileage allowance for attendance. Furthermore as the membership was classed as "resident" and "non-resident," the "resident" members paying $10 more per year as dues, there was ample ground for the desire of the "resident" members to control Society policies. All meetings of the Society, about twenty per year, excepting the annual conventions were held in New York City under the auspices of the national society. Of the twenty-seven annual conventions held prior to 1896, only three were held west of the Mississippi River, one at St. Louis, Mo., one at St. Paul, Minn., and one at Denver, Colo.

A growing recognition of the increase of non-resident members and of the need for a change in the form of organization of the Society to give them a proper voice in its affairs began to find expression in the middle nineties and led to the adoption of various amendments to the Constitution.

ESTABLISHMENT OF LOCAL SECTIONS

The establishment of Local Sections began with the recognition by the Board of the San Francisco Section in 1905. Members of the Society in St.

Louis had organized an association as early as 1888, with the result that in 1894 there were more corporate members in that city than in any one of forty-one states and territories of the Union, only New York, New Jersey, Massachusetts, Pennsylvania, Ohio, Illinois, and California having more members than the city of St. Louis. The second Local Section officially approved was the Colorado Section in 1909, and the third, the Georgia Section in 1912. In 1913 five more Local Sections were organized; in 1914, five, including the recognition of the old group at St. Louis; and twenty more were organized prior to October, 1921. Since then thirty Local Sections have been organized, making a present total of 63.

The creation of Local Sections was the fundamental change in organization which resulted in the Society becoming a truly national body. The bringing of the benefits of social and technical meetings to the members in all parts of the country has been a most important factor in the great growth of the Society and has made possible the radical changes in the Constitution which have been made in recent years. With twenty-one local groups established by 1918, holding meetings and discussing Society affairs, it naturally followed that the "non-resident" membership became more vocal and suggested the incorporation in the new Constitution of many ideas tending to a more democratic administration of Society business.

Also a marked change in the rate of increase in membership began with the establishment of Local Sections, in 1905, at which time there were a few more than 3 000 members. Membership reached 5 000 in 1909, 7 000 in 1913, and 10 000 in 1921. The growth in the sixteen years following the establishment of the first Local Section was twice as much as that of the preceding fifty-three years.

The Constitution of 1891 was amended eleven times between its adoption and the beginning of 1920, providing, among other things, a reduction in the number of Past-Presidents serving on the Board of Direction from all those living to the five who had last served the Society.

ESTABLISHMENT OF STUDENT CHAPTERS

The establishment of eight Student Chapters in 1920 and of thirty-one in 1921, followed by eighty more in succeeding years up to 1938, was a second radical organic change which had far-reaching results. The more than 5 500 students who were enrolled in these Student Chapters in the school year 1937–38 are not members of the Society, and a large majority of them probably will not enter as Juniors on graduation, but several hundred of the most promising leaders among them will take the easy way provided for entrance to the Junior grade immediately on graduation.

The benefit to the Society of this early contact with thousands of young men each year cannot be questioned. The results of the founding of Student Chapters have been to bring many practicing engineers into much closer touch with the colleges than would otherwise be possible, to give to college students a knowledge of the Society and its objectives, and to make the way into the Junior grade easy for college graduates. The Student Chapters form a great reservoir from which the Society will draw the larger part of its membership in the years to come.

In 1921 the Society had 458 Juniors, approximately 4½% of the total membership. In 1926 there were more than 1 000 Juniors, or 9½ per cent. In 1929, 2 000, or 15.4%, and, in 1933, we passed a membership of 3 000, or 20% of the total membership. On May 31, 1938, there was a Junior membership of 3 736, or 23.7% of the total membership on that date. This rapidly increasing number of Juniors and the steadily rising percentage of this group in proportion to the total membership is the direct result of the formation of Student Chapters. It indicates a continuous lowering of the average age of membership. It also indicates a steadily increasing percentage of young employee engineers in our membership. It creates a present problem but it also augurs well for the future of the Society if these young men can be put to work in and for the Society and can be given the maximum of benefit from their connection with it.

The Constitution adopted October 5, 1921, with the eight amendments which have been adopted to date, marks the final change from a local association to a national society. The democratic method of nomination and election by letter-ballot by members resident in each Zone or District insures a Board of Direction that is truly representative of each area. The provision for changes of District and Zone boundaries by the Board insures adjustment of representation in proportion as membership changes. The present Board with nineteen Directors, four Vice-Presidents, two Past-Presidents, and the President, not more than six of whom could possibly come from the New York metropolitan area, removes the last vestige of local control. The payment of mileage allowances sufficient to substantially cover the actual cost of attendance at meetings has resulted in the presence of from 80 to 100% of all members of the Board at all meetings of recent years.

Tables 1 and 2 present an analysis of the membership as of 1894, 1920, and 1938, three dates selected arbitrarily to show the classification and distribution of members (*a*) at the mid-life of the Society at a time when it was still essentially a local society although more than 60% of its members were "non-resident;" (*b*) in 1920 when many changes in the organic structure had been

ESTABLISHMENT OF TECHNICAL DIVISIONS

A fourth fundamental change in the Society organization came with the establishment of the Highway, Irrigation, Power, and Sanitary Engineering Technical Divisions in June, 1922. These have been followed by the creation of eight other Divisions, and still others are in process of formation.

The net result of the establishment of Technical Divisions has been to turn a large part of the technical programs of the annual meetings, annual conventions, spring and fall meetings over to the Divisions, and, more recently, to put them in charge of research committees dealing with matters coming under their jurisdiction. In effect, to the Divisions have been given the direction of the important technical work of the Society, placing each specialized field of activity in the hands of men whose life work and principal interest is in that field, and insuring to each full opportunity to hold sessions at every meeting where local interest calls for them.

The Technical Divisions will undoubtedly encourage the development of a number of highly specialized fields of engineering, induce the membership to do more work of research, and increase the quality and quantity of publication in the various special fields.

NEW PROBLEMS

The foregoing discussion has briefly outlined the fundamental changes that have taken place during the past forty-five years. They are changes made necessary by the growth of membership, the increase in the number of special fields in Civil Engineering, the development of the United States which has resulted in a great increase of engineering work, in the number of members of the Society in the Central, Southern, and Western States, and by the granting to members non-resident in New York a voice in Society affairs proportionate to their membership. These adjustments indicate healthy growth in the

Society and prove its ability to keep up with changing conditions in the profession and nation.

The Board of Direction has been continually on the alert to improve the Society and encourage greater activity among its members. There is need for constant introspection, frequent examination of methods of administration to see that old and obsolete practices are not continued, that there is no waste of Society funds through duplication of effort or through the doing of unnecessary things, and to insure the doing of all new things which the Society may with propriety assume to be within its province.

There are now three major problems before the Board:

I.—Local Sections.—How can these agencies be made of the greatest possible benefit to the membership? What duties and functions may properly be turned over to the Local Sections?

II.—Junior Members.—How can these young men be best assimilated in the Society? What methods shall be adopted to enable them to get the maximum benefit from their connection with it?

III.—Technical Divisions.—What form of organization is best adapted to carrying on the specialized technical work of the Society and securing adequate publication of worthy papers?

The objective that must be kept in mind is *maximum benefit to the individual members of the Society.*

I.—Duties and Functions of Local Sections

With the entire area of the United States and its possessions now assigned to the sixty-three Sections, and with a formula for allocation of funds by the Society to the Sections which assures sufficient to care for all current expense of postage and mailing of notices of meetings and frequent bulletins to all members resident in the area, and to cover the cost of many of the activities of the smaller groups, it is expected that there will be increased interest on the part of many of the Sections and a greater incentive for many qualified engineers who have not joined the Society to do so and take part in its work.

(*a*).—*Legislation.*—The legislative problems of the profession in any state can best be solved by the combined effort of the various engineering groups in the state. Such matters as securing proper registration laws; insisting on complete enforcement of such laws; the encouragement of the adoption of laws providing for the merit system in civil service; the establishment of a proper classification of engineering employees and the provision of adequate salaries for each class; insistence on the payment of reasonable salaries for all engineering service; safeguarding public positions in engineering by securing the enactment of legal requirements that only qualified registered engineers shall hold them; and other legislation in the interest of the profession are all matters in which engineers resident in the state can do much more effective work if properly organized for joint effort than can be done by reliance upon any national society. The latter can aid as a medium of exchange of information and can give support to local effort, but the work of local societies only can be truly effective. There must be continued watchfulness on the part of the profession in matters of legislation. Not only must good legislation be supported, but that which is injurious to the profession of engineering must be opposed.

(*b*).—*Membership.*—The membership of any professional organization can be expected to increase only when the activity of the organization is pronouncedly along lines that are of distinct benefit to the profession. Under the economic conditions now existing, and especially in view of the labor unrest and the activity of the labor unions, the national engineering societies, particularly those of the civil engineering branch, cannot confine their activities solely to technical papers and discussions. The social and economic problems of the members, especially of the younger men just coming into the profession, must receive the earnest thought of all engineers.

The American Society of Civil Engineers has never made a campaign for membership. Its specifications for membership in all grades are clearly written. The requirements are higher than those of any other engineering society. There are hundreds of engineers in the United States, doubtless many in almost all of the States, whose experience fully meets the requirements of the specifications of the Society but who for one reason or another never have joined.

Many men are reluctant to apply for membership unless spoken to by some member. There is no sound reason why a membership committee in each Local Section should not make a list of all engineers in the area, examine their qualifications, and when a man is clearly eligible for membership in one of the grades, see that some member of the Section suggests to him the desirability of applying for that grade.

In case such a plan is followed the greatest of care must be exercised to see that the applicant asks only for the grade for which he is fully and clearly qualified. Border-line cases should not be encouraged to believe that the Society's Committee on Membership is careless or lax, because it is not, and the award of full membership only comes to those who are fully and abundantly qualified.

(*c*).—*Students and Juniors.*—The Local Section is expected to take an active interest in all Student Chapters in its area. The college authorities will almost invariably welcome the active interest of practicing engineers in matters of engineering education and in the employment of graduates in engineering work. Many Sections award as prizes membership in the Junior Grade, paying the entrance fee and, in many cases, one year's dues. Sometimes the prize is given for the best paper written by a senior in each of the colleges; other Sections make the award for outstanding ability based on excellence of school work, activity in campus affairs, and notable work in public speaking.

Some of the Sections pay part of the expense of students to Student Chapter Conferences and in other ways show an interest in and encouragement of the work of the students for the Society. Every Section should make this work with Student Chapters a prominent part of its program of activity.

When the student becomes a Junior in the Society on graduation he is entitled to much more of the interest of the Local Section than he received when in college. He now rates in the membership, has his name in the Year

Book, and receives all publications. Under the Society's formula for return of money to the Section he counts the same as any other member.

No matter what form of Junior organization may be adopted in the Section the individual Junior is entitled to the full consideration of officers and members as one of the future leaders and workers of the Section, and he should be trained for that work.

Where there is an association of Juniors in a Section area there should be close co-operation on the part of the Local Section officers. Such a group must be kept as an essential and integral part of the Section, given financial aid by the Section, and its members encouraged to attend all Section meetings.

This work with young men is very distinctly personal work dealing with matters of social, financial, and economic interest. It is work that can be done in a satisfactory manner only by the Local Sections. A national society cannot possibly do it. No single formula can be developed for it because of the wide differences of conditions in the different states and section areas.

(*d*).—*Co-Operation.*—There is present need not only for strong and active Local Sections of the Society but for the most cordial co-operation of the Sections with each other and with Sections of other national societies and with state and local groups within the state, to the end that the united engineering profession in each state may be prepared to act whenever action is needed. The standing of the American Society of Civil Engineers is such that our membership and our Local Sections may properly be looked to for leadership in this matter of co-operation. In several states the Sections are now the recognized leaders in all matters affecting the welfare of the profession and handle all matters in a highly efficient manner. It is the task of the Society to build up strong and active Local Sections in all the states and to encourage them to take leadership not only in technical papers, publication, and research, but in the general social and economic welfare not only of their own members but also of the whole civil engineering profession in the state.

II.—Responsibility of the Society to Its Junior Members

Junior membership appears not to have been particularly attractive until after the formation of Local Sections. The number of Juniors increased rapidly from about 250 in 1893 to around 800 in the years 1911 to 1913; then for some reason the number dropped to less than 500 in 1920, 1921, and 1922.

The importance of Junior membership to the Society can hardly be overestimated. The class of young men in college which is attracted by membership in Student Chapters will be found to be the able and promising students whose interest in technical engineering is marked and who expect to go into engineering work. Those who apply for Junior membership in the Society on graduation are generally those with the highest grades, real interest in the profession, and reasonable assurance of a job.

These young men need the encouragement of the older members of the Society after they enroll as Juniors. Employee engineers all of them—frequently married shortly after graduation—with a limited income but with a keen interest in technical problems— and a desire to get the most out of engineering associations—they can be greatly helped by friendly recognition on the part of older engineers and by being given the opportunity to do active work in the Section and to have a part in the technical discussions.

Where there is a group of fifteen or twenty or more in a single city some type of association of Juniors appears to be the desirable form of organization. It offers to the young men the opportunity to prepare papers, take an active part in discussion, and really get into worth-while technical activity in a large way. Such an association also makes possible intimate social contacts among themselves. Then when they attend the Section meeting they extend their acquaintance with older men and get the benefit of both the technical and social activity of the Section. Where this solution is adopted the Section should have a contact committee and the Juniors should be assigned to Section committee work and given duty wherever possible with the older group.

Where the group of Juniors in a Section is small it would appear that a desirable policy is to give Juniors an active part in the work of the Section by putting one on each committee, designating them as aides to the Section officers and giving them places on technical programs. Such a plan will tend to hold their interest and permit them to develop as working members. There are thirty-three states which have at present less than 50 Juniors and thirteen states with more than 50. Six of these states have from 100 to 200 Juniors and four have more than 200.

This problem of Junior membership is one for each Local Section to solve for itself, but the correct solution is of vital importance to the Society. It is fair to assume that the opportunity to take an active part in the work of an association of Juniors whenever one is formed, will attract many young men who otherwise would not be inclined to join a Section made up of older practicing or employer engineers.

The important thing is that these young men are just entering the profession. Their concepts of professional ethics, of high standards of practice, and of engineering loyalty are being formed. They are entitled to proper classification of position and to adequate pay and a right to prove themselves worthy of advancement. They constitute the group that is most subject to irregularity of employment and to exploitation by labor unions. The inspiration that they can gain from membership in the Society, from the acquaintance with old and successful engineers, and from the advice and counsel of the members of the Section will be of lasting value in the making of the great engineers of a few years hence.

We may as well face the fact that, like it or not, the national engineering societies must give more thought to the economic and social problems of their members. Engineering is a great profession and to keep it so its members must recognize their responsibility to the younger men who are entering it. The engineering society is in fact, and must recognize itself as being, the graduate school in which young engineers gain that knowledge of professional relations, ethical conduct, and ideals of good practice that can be secured nowhere else.

III.—TECHNICAL DIVISIONS AS FUNCTIONING AGENCIES

For the first seventy years of its existence the Society asked its members to prepare papers and to discuss them, and published those passed upon as most meritorious. It made no distinction as between the different fields of technical interest and it had no committees or groups of its members engaged in the encouragement of specialization in engineering practice. Any study of American engineering literature would be compelled to give to the Society credit for the greatest contribution to engineering knowledge and to the literature of the profession in America made by any organized group of engineers. These papers were on all kinds of subjects and no one field had a monopoly of publication.

The Society has done a magnificent job, but in the doing of it failed to recognize sufficiently the divergence of engineering interest and the growth of many new fields of specialization.

In its early days the railroad engineers were most active in the work of the Society. In 1893 the Society's Committee on Standard Rail Sections made its report and the "A.S.C.E. Standard Rail Section" was laid on hundreds of miles of railway track. Apparently, the difficulty of securing the appointment of desired committees and of getting prompt publication of reports and manuals caused this group of members to foster the activity of a non-professional organization of railroad men and to change its entire character so that it ultimately emerged as the American Railway Engineering Association.

This Society could never have done what that great and active Association has accomplished in the standardization of railway construction and maintenance practice, but one wonders whether a Railway or Transportation Technical Division, if it had been established forty years ago, might not have afforded a medium for individual discussion of railway problems that would have attracted hundreds of qualified engineers to our membership who have never joined because A.R.E.A. with its intensive committee work absorbs their time and interest. The A.R.E.A. does not afford opportunity for much individual expression of opinion, however, nor does it encourage the writing of papers by its members on topics of general interest in transportation.

The question may well be asked whether or not the other Founder Societies also have been remiss in not caring for specialized fields of technical interest much earlier than they did. Could not the work of such organizations as the American Society for Testing Materials, American Welding Society, American Society of Refrigerating Engineers, American Society of Heating and Ventilating Engineers, American Illuminating Society, and American Society for Metals, and other highly specialized technical groups, have been done just as well by wisely organized technical divisions of some of the Founder Societies? It would appear that some of these organizations could do just as much good work and do it even more effectively and economically as Divisions of the great engineering societies.

We now have twelve Technical Divisions and requests for more. There may be some overlapping and duplication in existing Divisions. There may be other agencies in the Society capable of doing some of the work which the proposed new Divisions contemplate undertaking. Certainly, there is need for the Committee on Technical Procedure to make a careful study of the Divisions with a view to possible improvement of the technical work of the Society.

Although the provisions of the By-Laws of the Society are apparently broad enough to meet all requirements, it appears to be possible to improve the organization of the Divisions. For example: We have a Highway Division. Might not a Transportation Division, with sections or sub-sections dealing with Railways, Highways, Highway Transport, and Waterways, each working independently in its own special field but keeping close contact with the other transportation interests, be more effective in finally helping to solve the great problem of internal transportation which confronts the nation?

It appears certain that the splendid work of our Sanitary Engineering Division is just as good as it would be if the same men were organized as an American Society of Sanitary Engineers, and the chances of just as wide publicity and publication ought to be available to them at much less cost than if organized as a separate society.

These problems call for careful study by the Board, the various committees, and by interested members. The past history of this Society makes it clear that they can be fairly and justly solved.

Technical papers and discussions at all conventions and regional meetings are under the supervision of the Divisions. Fact-finding and research committees dealing with any specialized field should be under and report to the officers of the Division in charge of that field. In other words, each Technical Division should be in effect a technical agency operating within the American Society of Civil Engineers, and making use of its organization, staff, and publications.

THE SOCIETY AS IT FUNCTIONS NATIONALLY

All matters of general Society policy, qualifications for membership, election and transfer of members, establishment of standards of ethics and practice, the general administration of the affairs and property of the Society, publications, relations with other societies, maintenance of all joint agencies through which the national societies are co-operating, all matters of national legislation, and all dealings with departments or bureaus of the federal government, are functions of the Board of Direction. Under no conditions should any group, either Local Section or Technical Division, undertake to speak for the Society, other than as an authorized spokesman on matters that have been determined by action of the Board of Direction.

The tendency of all changes in the organic structure of the Society in past years has been in the direction of one large, dignified national society with uniform and high standards of individual membership, having numerous state and metropolitan subdivisions, each one freely acting in matters of social and economic interest to the membership in its own area, and co-operating with other professional organizations within the area for the good of the engineering profession.

In the future as in the past it is probable that a great number, if not a majority, of the most important technical papers, those which are entitled to rank as monumental contributions to the advancement of technical knowledge, will be submitted by members of the Society who have devoted long study and research to some special subject and have given time and care to the preparation of the paper. Such studies rarely fit into the program of a meeting or convention. They are submitted to the Society for publication as a matter of long established custom rather than of special invitation.

The technical and social programs of each Local Section are under the control of the Section. The major technical programs of the quarterly meetings of the Society, each in charge of a Technical Division, and independent papers of members of the Division based upon or prompted by the research work of the Division, furnish a large part of the material published in *Civil Engineering*, with more highly technical papers appearing in *Proceedings* and *Transactions*. The high quality of the publications of the Society has been maintained for more than half a century and needs no comment.

With such an organization as has been described, with a loyal membership made up of the leading civil engineers in the country, uniformly strong in all the states, financially sound, and with well established and favorably known publications, the American Society of Civil Engineers is, as it should be, the one professional society which is in the best position to help the individual members of the civil engineering profession in difficult times like the present. It should assume leadership in many matters. It should by its example develop a spirit of co-operation among all the engineering organizations.

The wide differences in the fields of technical engineering make it unlikely that there will ever be one all-inclusive national organization of engineers. The other great national societies will inevitably gain in numbers and strength as other fields of engineering continue to increase in importance.

Every state and every large city has a goodly number of engineers and men who are intimately connected with engineering work and keenly interested in it, none of whom is eligible for membership in the national societies. This fact is responsible for the existence of the more than forty state and nearly one hundred and twenty-five local engineering societies, all of which number in their membership many who belong to this and the other national organizations.

Most of these state and local societies have a real service to perform, and none of them is in any sense a competitor of this Society. It is with these groups, as well as with Local Sections of other national societies, that our Local Sections must work and co-operate on all matters of legislation and welfare.

The most annoying problem of the present day is that of Unionization. With labor leaders active in the attempt to bring every employee group into some form of union organization, with political and official pressure being brought to bear in some states or cities to compel such affiliation, many young engineers and employees in sub-engineering positions need some professional society or group to turn to for advice and support.

The true answer is that Engineering is a profession and not a trade. The labor union or trade union does not solve the engineer's problems, and he has no rightful place in the unions because his professional obligation makes him the arbitrator or umpire between the owner and builder, or the public and the contractor on public works. Unless the engineer is a member of a professional society which can and will speak for him, and unless his society has the support and backing and hearty co-operation of the other societies of the profession in that state, he has little chance of having his argument listened to.

The time is apparently here when the engineers of the United States must take the position very definitely that engineering is a profession—yes—a learned profession reached only by years of study and training and experience in design, construction, or research, and that the obligation placed on the engineer by his profession to exercise independence of judgment, to be fair and impartial, honest and unbiased in all matters with which he deals is wholly inconsistent with any form of employee unionism. The obligation is just as binding on the engineer employee of the railroad, power company, city, state, or manufacturing plant as it is on the consulting engineer.

And if it be true that these problems face the profession to-day then it is equally true that the profession must speak through its societies. The societies can no longer devote themselves exclusively to matters of technical theory, construction methods and materials, or of design and research. They must give more thought to registration and the enforcement of registration laws; to the merit system in civil service; to proper classification of employees, and not only to the fixing of adequate salaries for each class, but to insisting that those salaries be paid. They will have to give thought to such matters as political discrimination against engineers, unjust discharge, and many other matters that involve the relationships of the engineer employee of city, state, or federal government.

The American Society of Civil Engineers has been doing several of these things during the past six or eight years. If present conditions persist this Society and all other engineering societies will have to do them in an organized way and to a much greater extent if the young engineer or the employee engineer is going to have his profession speak for him with the same degree of authority that the trade union speaks for its member.

This concept of Society activity is repugnant to many members of the profession. Perhaps the civil engineers need these things to a greater degree than others because they are to a much greater extent employed in public service. During recent years the American Society of Civil Engineers has acted in these matters through its Board of Direction and a few of the large metropolitan sections. If such things are to be undertaken successfully the Board of Direction must have the whole-hearted co-operation of all the Local Sections in carrying it out. The Board cannot do it alone. The Society and all of its sixty-three branches must co-operate actively.

It would appear to be self-evident that any engineering society to achieve real success must be primarily a technical society having as its objective the highest standards of technical, professional, and ethical practice. Furthermore, it should deal with all economic problems which are involved in engineering construction and should fearlessly express its opinion and assume leadership in the formulation of broad economic policies of state and national interest. There is no sound reason why such a society cannot and should not, through its Sections, extend its activities to include also all matters which have to do with the financial and economic well-being of its members. Failure to do so will result in the attempt to organize new societies with this objective and it is obvious that in times like these the long established and financially solvent Founder Societies are in much better position to accomplish definite results than any new group whose energies must be devoted largely to organizing and securing members.

The American Society of Civil Engineers has a record of eighty-six years of fine accomplishment. It has a loyal membership, several thousand of whom have been members for many years, a thousand who have loved the Society and supported it for a third of a century.

The standards of membership qualifications, of ethics, and of professional practice have always been of the highest, and every change in the past has been to raise these standards. They should never be lowered. The Society is aristocratic in the sense that it takes into its membership only those who have proved themselves to be of high personal and professional standing. The traditions of the Society must be kept.

It is respectfully submitted that it is such an organization, and only such, that should be looked to for leadership by the engineering profession; and this leadership must be in all matters that pertain to the social, economic, and political welfare of the Engineer as well as in his practice, ethics, and scientific perfection.

STANDARD PRACTICE IN SEPARATE SLUDGE DIGESTION

FINAL REPORT OF THE COMMITTEE OF THE SANITARY ENGINEERING DIVISION ON SLUDGE DIGESTION

INTRODUCTION

Satisfactory disposal of sludge is an important part of the treatment of sewage, from the standpoint of cost as well as of sanitation. It has long been a difficult problem, and many processes and combinations of processes have been experimented with and developed.

At present, primary sludge is usually digested in separate compartments or in the lower part of an Imhoff tank, dried on sand beds, and disposed of either as waste or as fertilizer. Mechanical dewatering is being used as an alternate to the sand-bed for large projects. Activated sludge is frequently dewatered, dried, and sold as fertilizer, but it, also, may be digested with primary sludge in separate tanks.

Although there is doubt as to the first use of the method known as separate digestion, several of the earliest sludge-treatment plants employed it. The late Rudolph Hering, M. Am. Soc. C. E.,[1] states that, in 1884 and 1885, separate digestion tanks were used in tests at the Pimlico Pumping Station, in London, England, under the direction of Mr. W. J. Dibdin. The method was again used about 1899, at the Lawrence (Mass.) Sewage Testing Station, and the results are discussed in the Annual Reports for that Station for 1899 and 1900.

In the first decade of the present century, Imhoff and Travis developed the 2-story tank. Most of the sludge-digestion plants installed during the second decade were of that type, but since about 1920 the trend has been decidedly toward the adoption of the separate system; at present, several hundred such plants are in operation in the United States.

Structures and equipment for separate digestion of sludge may account for from 20 to 35% of the total cost of the sewage treatment works. They include digestion tanks, storage tanks, pumping stations, drying beds, meters, boilers, buildings, etc. Ample capacity and good design as to detail of

---

[1] *Engineering News*, August 14, 1913.

arrangement and of mechanical equipment are required, as a deficiency in these points not only hinders digestion, but may result in reducing the efficiency of sedimentation and other processes thus lowering the entire standard of plant operation.

Good design alone is not enough, however; even in the best plant, satisfactory operation depends upon the operator's knowledge of the basic principles involved, and upon his constant attention to the proper methods of testing and routine procedure.

Adoption of the separate digestion method and progress in sludge-treatment research have been so rapid that on the whole neither the principles of design nor the methods of operation have been thoroughly correlated. The purpose of this report, therefore, is to state the fundamental aspects of sludge digestion and to assemble in useful form worth-while information relating to the design and operation of separate sludge-treatment plants.

The outline and general content of this Final Report is the same as the Progress Report published in 1937[2], with several essential additions and corrections. The report begins with a description of sewage and of the end products of digestion—gas and digested sludge. Important environmental factors in the digestion process are then discussed. Next, the various types of sludge-digestion and gas-utilization structures and equipment are described, and methods for computing the required capacity of tanks and heating units are presented. The following section outlines the various proposals for disposing of sludge after digestion, and the report closes with a discussion of operating routine. Two Appendices are included, giving data on the operation of typical plants.

I.—CHARACTERISTICS OF SEWAGE AND OF THE END PRODUCTS OF DIGESTION

Sewage

The water-borne wastes of a modern city are made up of such a great variety of compounds that only a general discussion of sewage characteristics is practicable. Data on the composition of sewage have been secured from thirty cities representing a total contributing population of 4 760 000, and are summarized in Tables 1 and 2. It will be noted that the average daily flow per capita varies from 306 gal to 48 gal, and that a marked trade-waste contribution was reported by nine cities, while this factor was negligible in the others. Fifteen of the cities reported combined sewerage systems, and fourteen, separate systems.

Waste products are present in sewage as solids, colloids, and solutions. The solids, in turn, may be classified as volatile or organic, and fixed or mineral (sometimes called "inert"); or, with respect to their settleability, they may be graded from the readily settleable to the practically non-settleable. Colloids ordinarily undergo a marked reduction when sewage treatment is carried to a high degree of purification. The reduction, however, can not be accomplished by sedimentation unless that process is preceded by some special treatment adapted to that end. The materials in solution, also, are obviously not susceptible to removal by plain sedimentation, although certain of the soluble ingredients of the incoming sewage may stimulate sedimentation. (They may also retard or accelerate the digestion of the sludge.) Any changes that the dissolved wastes undergo in their passage through the settling tanks is due to bio-chemical agencies.

---

[2] *Proceedings*, Am. Soc. C. E., January, 1937, p. 39.

One factor having an important bearing on the accuracy and comparability of analytical data is the state of comminution of the solids in the samples on which the data are based. A sample from sewage in which very little comminution has taken place may be too high or too low in solids,

depending on whether or not the coarse particles happen to have been included. More truly representative samples may be obtained in cases where the sewage has been subjected to pumping, or to flow at high velocity, or even simply to flow through a great length of sewer, for in such cases the suspended-matter content is likely to be more evenly distributed.

Other conditions influencing the reliability of data are: (1) Correctness of the measurement of flow and of the count of the contributing population; (2) the method of sampling and the number of samples taken; and (3) the accuracy of the analytical methods.

It will be noted that twenty-two cities reported settleable solids in cubic centimeters per liter, and six in parts per million. The latter method has the advantage of expressing the results as a definite quantity, but the data are not as valuable as they would be if this method were in general use, because the results cannot be compared with those expressed in cubic centimeters per liter.

Organic nitrogen	16	2 606	48.8	5.2	22.1	0.041	0.004	0.018

* Values are in cubic centimeters per liter. † Values are not parts per million.

Digested Sludge

The characteristics of digested sludge depend largely upon whether the contributing sewerage system is separate or combined, and upon the proportion of industrial wastes and the degree of treatment of the sewage. Sludge from combined sewers usually contains more mineral matter and less moisture than sludge from separate sewers. Abnormal quantities of oil, iron, or other chemicals may be due to industrial wastes. Fine screening, skimming, or removal of detritus in preliminary tanks will reduce the quantity of coarse suspended solids in the sludge.

Color is somewhat of an indicator of the degree of digestion, well-digested sludge being usually quite black or very dark gray. Color, however, depends somewhat upon local conditions—particularly upon the type and quantity of industrial wastes. The moisture content of digested sludge should be less than that of fresh sludge, although the reduction in some cases is not great. In general, well-digested sludge has the following characteristics:

Physical.—

(*a*) Texture: Uniform, black or dark colored, with no visual evidence of fresh sewage solids, such as feces, paper, or grease.

(*b*) Density: Thick; the moisture content of sludge on withdrawal from the tanks is generally not more than 90 per cent. (Sludge with as much as 95% moisture, however, may be thoroughly digested.)

(*c*) Odor: Faintly tarry; practically unobjectionable. After draining or drying, well-digested sludge should have an earthy or musty odor.

(*d*) Ability to drain on sand-beds: Good.

Chemical.—

(*a*) Mineral matter content: Substantially greater (expressed as a percentage) than that of the fresh sewage solids.

(*b*) Volatile matter content: 50%, or less than 50%, of the volatile matter content of fresh sludge.

(*c*) Organic content (of sludge removed from the drying beds): Not generally more than 50 per cent. The bio-chemical oxygen demand of this content should be substantially lower than that of the fresh solids.

(*d*) Hydrogen-ion concentration: pH usually between 7.0 and 7.6; that is on the alkaline side of neutrality.

It should be noted that the process of digestion reduces the value of the sludge for use as fertilizer by as much as two-thirds, because of the gasification of organic matter containing nitrogen.

Gas

Gas produced during the digestion of sludge consists principally of methane (CH_4) carbon dioxide, and nitrogen, but includes also small quantities of hydrogen, hydrogen sulfide, and other gases. Although the composition depends upon the character of the sewage and the stage to which digestion has progressed, the particular sources of the various constituents are not definitely known.

Table 3 shows the analyses of gases collected at various sewage works. The average composition, based on the data there given, is approximately 68% methane, 25% carbon dioxide, 5% nitrogen, and 2% hydrogen. In general, gas obtained at German installations contains more hydrogen and hydrogen sulfide than that produced in the United States.

TABLE 3.—AVERAGE ANALYSES AND HEAT VALUES OF GASES COLLECTED AT SEWAGE TREATMENT WORKS*

(Gas from Separate Digestion Tanks Unless Otherwise Noted)

---

* Quantities and temperatures for German localities were converted from cubic meters or degrees Centigrade.

[a] Approximate. [b] About 45 000 human population plus 67 000 population (equivalent of industrial wastes). [c] High iron content. [d] Mixture of primary and activated sludge. [e] Gas collected from portion only of contents. [f] Sludge which has been warmed by steam is added in water. [g] Winter and summer, respectively, due to warm industrial wastes. [h] Assumed value. Gas quantities not available due to leakage. [i] In addition, packing-house wastes were partly treated. [j] Cooling water from gas engines was used to heat two digestion chambers. [k] Caused by warm wastes from wool washery. [l] Not all the gas was metered. [m] Three Imhoff, two separate, one Neustadt, one Stuttgart, and one supplementary tank. [n] Sludge heated before being added to tanks. [o] Gas utilized. No record of gas wasted.

Heat value varies almost directly with the percentage of methane, although the hydrogen content, while small, has some effect. The heat value of gas from the installations reporting in Table 3, is grouped and averaged as follows:

Group	Average Btu per cubic foot
European	738
United States:	
Imhoff	789
Separate	639

In their early studies, Buswell and his associates assumed that the weight of gas produced was equal to the summation of the weights of protein, grease, cellulose, and crude fiber digested. Buswell later found that the higher fatty acids of grease produce more than their equivalent weight of gas, because more or less water enters into the reaction. The quantity depends upon the number of carbon atoms in the acid. Buswell and Pearson obtained 1.25 lb of gas per lb of volatile matter digested, at Champaign-Urbana, Ill.

Information relating to quantities of gas collected at various sewage works has been assembled in Table 4. It is apparent that no averages can be made which are of general applicability, because the characteristics of the local sewage are so different. The average of certain groups is indicated as follows for those plants listed in Table 4:

Group	Cubic feet of gas per capita per day
Germany:	
Unheated tanks	0.41
Heated tanks	0.53
United States (excluding Cedar Rapids):	
Imhoff	0.55
Plain sedimentation	0.76
Trickling filters	0.92
Activated sludge	0.91

At Antigo, Wis., Cedar Rapids, Iowa, Chicago, and DeKalb, Ill., the gas production is high, possibly because of the nature of the industrial wastes in the sewage.

II.—ENVIRONMENTAL FACTORS

Among the environmental factors that have an extremely important influence on the bio-chemical processes of sludge digestion may be mentioned the temperature at which digestion is carried on, the hydrogen-ion concentration and the percentage of return sludge (reaction and seeding), and the trade-waste content. Other environmental factors of less importance include pressure and density. All these factors are considered in the following paragraphs. Attention should first be called, however, to the fact that the properties of the influent to the sludge digestion equipment may themselves have a decided effect on digestion. These properties depend on the nature of the processes to which the influent has already been subjected. Thus, if the influent comes directly from primary settling tanks through which crude sewage flows, it will consist almost entirely of fresh, or primary, sludge. On the other hand, if primary settling tanks are operated as septic tanks, a partly digested sludge will result, that may be termed septic sludge; it will ordinarily be a mixture of relatively fresh and quite well-digested sludge, the proportion depending largely upon operating conditions. Still other general types of digestion-equipment influent are secondary sludge (from final or secondary settling tanks following filters) and activated sludge (from settling tanks following aeration tanks).

TEMPERATURE

Temperature has been found to have a considerable influence on the time required for sludge digestion, as it determines to a large extent the type of organism that predominates in the sludge. The importance of this factor has led to considerable investigation.

Until a few years ago, prior to the time of temperature control, sludge digestion was carried on at or near the temperature of the sewage, or from about 50°F to 70°F, and in the early investigations of temperature control, the optimum temperature was considered to be about 82°F. Recent investigations have indicated, however, that a temperature of 110°F to 130°F makes possible a still shorter digestion period. Digestion at these higher temperatures has been designated as thermophilic digestion. Less information is available on results at intermediate temperatures. There are not enough operating data from large-sized plants to justify a final conclusion as to the best and most economical temperature. Present information indicates that temperatures between 80°F and 95°F are desirable. Savings in cost and improvement in operating conditions with temperatures in excess of 100°F have not been established.

Some data on the relation between temperature and the time required for digestion are illustrated by Fig. 1. In addition to the effect of temperature on the time, and hence on the capacity, required to bring about a satisfactory reduction in volatile matter, the effect on quantity and rate of production of gas is also important. The rate of gas production appears to be greater at the higher temperatures, and Willem Rudolfs, M. Am. Soc. C. E., states that the total quantity per unit of volatile mater is also greater, although the evidence supporting such a conclusion is as yet limited.

The percentage of reduction in 108 days in the volatile content of sludge, unseeded but with pH-adjustment, at different temperatures, was stated by Rudolfs as follows:

Temperature: In degrees Centigrade	In degrees Fahrenheit	Percentage reduction in volatile matter
10	50.0	16
18	64.4	26
24	75.2	58
29.5	85.1	64
35	95.0	54

Heukelekian[3] states that with temperature control at 70° F, the digestion period is about 35 to 40 days, but he declares confidently that it is possible to draw ripe sludge 24 hr after the addition of the raw material, provided there is ripe active thermophilic sludge and the temperature is maintained at approximately 120° to 125°F. According to Heukelekian:

> "The sludge will be just as ripe as that drawn at the end of 35 to 40 days at 70°F. It will have an ash content of 45 percent, or more, a pH of 7.8 or more, and a B.O.D. [bio-chemical oxygen demand] per percent of organic matter of 1 500 ppm, or less."

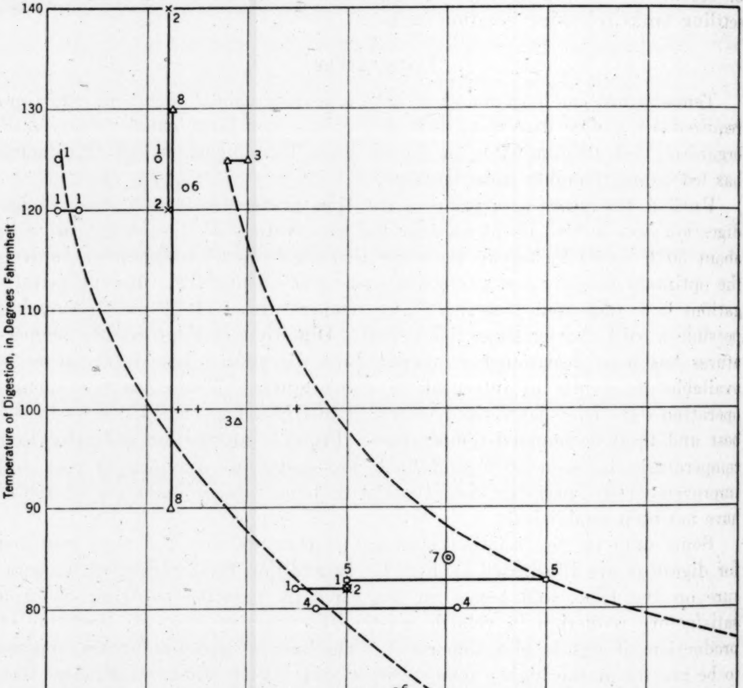

FIG. 1.—EFFECT OF TEMPERATURE ON SLUDGE DIGESTION: 1, HEUKELEKIAN (*Sewage Works Journal*, January, 1931); 2, NEW JERSEY SEWAGE EXPERIMENT STATION (AM. SOC. C. E., COMMITTEE, 1930); 3, RUDOLF AND HEUKELEKIAN (*Industrial and Engineering Chemistry*, January, 1936); 4, HEUKELEKIAN (*Sewage Works Journal*, July, 1930); 5, KEEFER AND KRATZ (*Sewage Works Journal*, July, 1930); 6, HEUKELEKIAN (*Sewage Works Journal*, April, 1930); 7, INDICATED AT GRAND RAPIDS, MICH.; 8, AURORA, ILL. (*Water-Works and Sewerage*, June, 1931)

In discussing the foregoing, Rudolfs states:

"If under ordinary 82°F temperature 50 to 60 percent of the volatile matter is decomposed in 25 to 30 days, about 70 to 75 percent is destroyed at

---

[3] "Digestion of Solids between Thermophilic and Non-Thermophilic Range," *Sewage Works Journal*, September, 1933. (Heukelekian found little difference between digestion at 20°C (82°F) and 42°C (108°F).)

120°F in 1 to 3 days * * * if at 82°F the quantity of gas amounts to 6 cubic feet per pound of dry volatile matter, it will be about 7 cubic feet under thermophilic conditions."

At Aurora, Ill., digestion is reported to have been accomplished in 12.5 days at temperatures ranging from 90°F to 130°F.

Keefer and Kratz[4] found that, for Baltimore, Md., sludge, seeded with 50-day digested sludge in the ratio of 2 parts of raw to 1 of seeding sludge, digestion was more rapid at 37°C than at 27°C, but the difference in rate was not great.

In 1930 a committee of the Sanitary Engineering Division of the Society summarized the results obtained at the New Jersey Sewage Experiment Station, as follows:

Temperature in degrees Fahrenheit	Number of days required for digestion
55	120
68	42
82	30
120–140	12
170	11

The actual operating temperatures in several large sludge digestion tanks are shown in Table 5.

TABLE 5.—DIGESTION TANK TEMPERATURES, IN DEGREES FAHRENHEIT

Month, in 1933	Aurora, Ill.	Springfield, Ill.	Rockford, Ill.	Grand Rapids, Mich.	Peoria, Ill.	Erie, Pa. (1932)
January	89	73	80	83	89	67
February	83	75	81	87	89	70
March	82	81	82	84	89	71
April	75	80	86	83	90	67
May	74	80	92	88	90	....
June	78	85	92	91	87	78
July	85	94	88	94	89	81

December	90	88	93	85	90	71

Among the considerations that should be taken into account in selecting an operating temperature, and in designing digestion tanks, are:

(*a*) The balance between the cost of providing extra capacity for digestion at a lower temperature and that of extra equipment for heating and insulating at a higher temperature, due consideration being given to the value of the additional gas.

(*b*) The capacity of the selected type of tank for being heated and for retaining heat.

(*c*) The method of heating and rate of transmission of heat.

---

[4] "Digesting Sludge at 37° C," *Sewage Works Journal*, March, 1933. (Keefer and Kratz found some advantage in digestion at 37° C (98.6° F) as compared to digesting at 28° C (82° F).

(*d*) The effect of higher water temperatures on the rate at which sludge cakes on heating coils.

(*e*) The effect on the heat balance of the concentration of solids in the tank sludge and in the fresh sludge.

(*f*) The heat lost with the sludge liquor and the possibility of some recovery by heat exchange.

(*g*) The effect of more active gas release on the area and depth of the tank and on the formation of scum.

(*h*) The need for and the relative cost of winter storage.

(*i*) The fact that the total size of sludge digestion and storage tanks is not directly proportional to the time required for digestion.

(*j*) The effect of the duration of low winter temperatures on the relative costs of operation at different temperatures.

Reaction and Seeding

Freshly settled sewage solids are normally alkaline or neutral. The pH-value may vary from 6.8 to 7.2 for solids from domestic sewage. Within the first 24 hr this reaction begins to change toward the acid side, and the longer the solids are held in a settling tank the more acid their reaction becomes. If no seeding sludge is present the solids undergo a period of acid fermentation before true digestion occurs. If suitable seeding sludge is present this acid phase is shortened or eliminated. There are, therefore, two courses of sludge digestion. Acid sludge is developed and digestion delayed when a digestion process, either Imhoff or separate, is started. After ripe sludge is developed this acid condition is restricted and digestion is greatly accelerated. If solids are held for many hours or days, either in sewers or in plain sedimentation tanks, acid sludge will be produced and discharged into the digestion tanks.

The formation of acid in unseeded sludge in process of digestion was studied in Germany 15 or 20 yr ago. Thumm and Reichle, in 1914, noted an acid reaction accompanying poor digestion, and recommended the addition of lime to the sewage.

The first study of the pH-value of fresh solids undergoing digestion was reported by Rudolfs in 1924. Solids collected from the Plainfield, N. J., sewage, which is from separate sewers, were digested at 20°C. Initially 6.4, the pH dropped to a minimum of 4.9 in 9 days, increased to 6.0 in 48 days, to 6.8 in 66 days, and to 7.0 in 120 days. In studies by Fair[5], of the digestion of fresh sewage solids from separate sewers at Brockton, Mass., the initial pH of 6.4 dropped to the very low value of 4.7 in 20 days, recovered to 6.4 in 35 days, to 6.8 in 60 days, and reached a maximum of 6.9 in 70 days. Keefer and Rudolfs report very prolonged acidity with unseeded Baltimore sludge from separate sewers. Solids from the primary settling tanks were pumped into a large open tank and allowed to digest without any seeding material. The pH initially was 6.1 and the volatile matter 65 per cent. The pH fluctuated between 5.5 and 7.3 for the first 200 days, then dropped to 5.6 in 300 days, and 5.2 in 400 days, and slowly rose to a maximum of 6.8 in 830 days. The prolonged acidity was probably due to lack of seeding material and to the low temperature in winter.

---

[5] "Time and Rate of Sludge Digestion and Their Variation with Temperature," *Sewage Works Journal*, January, 1934. (Fair and Moore find four zones of temperature with optimum for non-thermophilic at 33°C (91°F).)

On the other hand, the sludges used in the experiments reported by Zack and Edwards, from combined sewers contributing to the Des Plaines Treatment Works of the Sanitary District of Chicago, did not produce high acidities even when unseeded. The fresh solids had a pH of 6.3 when incubated at 25°C, and this value rose to 7.0 in 13 days. The fresh activated sludge had an initial pH of 7.3, which decreased to 6.6 in 10 days and then quickly rose to 7.0 in 20 days. The volatile content of the fresh solids was 67%, and that of the activated sludge was 60 per cent.

The acidity produced by unseeded solids apparently increases greatly if the initial pH is low and the volatile matter high. From a practical standpoint this means that solids high in organic matter, from separate sewers tend to produce greater acidity than solids from combined sewers normally lower in organic matter. Proper seeding, therefore, is more necessary with highly organic solids.

Storage of solids in settling tanks is undesirable, since the acidity increases, and lengthens the period of digestion if seeding material is insufficient. Fair and Klein show that digestion of unseeded solids is greatly retarded if the fresh solids are held until high acidity develops. They state that "it seems desirable that the settling solids reach the digestion tanks as soon as possible."

Undoubtedly, therefore, it is desirable, in separate digestion, to remove the solids from the settling tank as promptly as possible. The production of acid sludge should be prevented throughout the entire digestion cycle; therefore, the initial solids should not be allowed to become acid if it is practicable to prevent it.

Sewage solids do become acid, however, when there is not enough ripe sludge available to prevent acid decomposition. This occurs (1) when digestion tanks are first started: (2) when ripe sludge is lost by improper operation; or (3) when acid industrial wastes are present. From the results of analyses of gas from various digestion tanks, Buswell concludes that a high CO_2 content of the gas may serve as an index of improper seeding conditions, as correlated with acidity shown by pH.

When ripe sludge is not available, lime is commonly used for neutralization of acidity. The experience of a number of plant operators as reported by Bachmann indicates that liming is a useful remedy under abnormal conditions, but hardly to be recommended, from a practical standpoint, for normal operation.

When well-digested sludge is mixed in proper amount with fresh sludge, the reaction of the mixture and the course of digestion are different from those of unseeded sewage solids. Dr. Imhoff states:

> "Basically different from acid fermentation is the second kind, that establishes itself in well-conditioned digestion tanks. It results in the formation of carbon dioxide, nitrogen and, above all, methane (marsh gas), the

latter constituting about 75 percent of the gas by volume. The pH-value consistently remains slightly above the neutral point. The process is odorless and is called alkaline or methane fermentation."

The low pH of unseeded solids is caused primarily by the formation of fatty acids that decompose very slowly, but that must be decomposed before digestion is complete. In the presence of well-digested sludge, these acids decompose more quickly, and, in addition, the reserve alkalinity or buffer action of the digested sludge neutralizes them to a varying degree, depending upon the composition of the inorganic solids in the digested sludge.

The proportion and the character of digesting sludge in the tank are important. Rudolfs found in his earlier work that, at 70°F, the daily additions of fresh organic solids should not exceed 2% of the weight (dry basis) of the organic matter in the digesting sludge. In a later work, he has shown that this ratio might be increased greatly (the ratio in general falls between 2 and 6%) by increasing the temperature and, if necessary, adding lime. The use of lime is not recommended as a routine procedure, however.

Ripe sludge used for seeding must obviously be neutral or slightly alkaline in order to provide the proper buffer action or to neutralize the acid reaction of raw sludge. Its moisture content, within normal limits, is immaterial, but it should be actively digesting sludge.

TRADE WASTE CONTENT

Trade or industrial wastes originate from a great variety of manufacturing processes and have widely differing characteristics. When such wastes are mixed with domestic sewage the quantity of sludge is increased, the extent of increase depending on the characteristics of the particular wastes. The effect of industrial wastes on the process of digestion may vary over a wide range from somewhat beneficial to very detrimental, depending on the characteristics of the industrial sewage, the pre-treatment it has received, and the relative quantities of industrial waste and domestic sewage.

The effects of various industrial wastes on sludge digestion are summarized in Table 6.

PRESSURE

The pressure on sewage solids undergoing digestion results mainly in common practice from the depth of the digestion tank. In one of the shallowest 2-story tanks (at Schenectady, N. Y.) the liquid depth is 13.8 ft, and in one of the deepest (at Rochester, N. Y.), it is 33.9 ft. Most separate digestion tanks have depths of 20 to 30 ft. The pressure may be changed by applying a negative pressure (vacuum) or a positive pressure to the surface of the digesting sludge.

The major possible effects of pressure on sludge digestion are: (*a*) The effect on the biological life and its activities; (*b*) the effects on the gas produced by digestion, as, for example, the rate of gas production, the solubility of the gas, the size of the bubbles, and their motion in the liquid; and (*c*) the effect on the density of the sludge.

Other possible effects, believed to be of minor importance, are the pressure on the viscosity and on the surface tension.

TABLE 6.—EFFECTS OF VARIOUS INDUSTRIAL WASTES ON SLUDGE DIGESTION

Source of wastes	Quantity of sludge produced	Characteristics of sludge	Remarks
Bleacheries........	Small............	Usually alkaline; may contain disinfectants.	The waste contains soaps and decoloring agents.
Canneries..........	Usually large (depends on material canned).	Contains both carbonaceous and nitrogenous organic matter; develops organic acids in digesting.	It is usually necessary to provide preliminary treatment of cannery wastes before mixing with domestic sewage. These wastes are likely to cause foaming and scum.
Creameries and dairies	Depends on treatment process.	Fats and sugars break down forming organic acid, delaying digestion and causing obnoxious odors.	Organic acids that are generated coagulate the casein, which rises to the top as scum that does not digest readily.
Corn-starch plants	Variable, depending on process at corn - products plant.	Contains residual SO_2 which breaks down during digestion to form H_2S.	There is a tendency for sludge to bulk in aeration tanks.
Coke, coal, gas, and creosoting plants	Small............	Contains phenols and other compounds having germicidal characteristics.	This sludge will not digest. Normal domestic sewage sludge will digest if this type of industrial waste does not exceed 2% by volume.
Dye-houses........	Small............	Usually acid, and likely to produce offensive odors.	Will not interrupt digestion if dilution is large.
Meat packing plants.	Large............	Organic matter of high nitrogen content. Also, fats, hair, and paunch manure.	Much of the packing-house sludge digests with difficulty, if at all. Treatment at the source is desirable before mixing with domestic sewage.
Oil (crude oil, fuel oil, and spent crank-case oil)	Variable..........	Relatively inert chemically.	Interferes with digestion by surrounding the sludge particles, preventing proper drainage, and forming undesirable scum.
Paper and pulp mills (strawboard waste)	Very large........	Contains fiber and chemical residues. Sulfite wastes are germicidal.	Sludge digests slowly if at all. Most of the solids in waste from paper mills have commercial value and may be recovered by use of "save-alls", or similar equipment.
Pickle. Liquor; Iron	Variable.	Strongly acid. If neutralized by alkalinity of the sewage or by lime, iron compounds precipitate and form sludge.	The precipitated iron compounds do not interfere with digestion of the domestic sewage solids. The iron floc may be quite bulky. Treatment at the source is desirable.
Tanneries..........	Large............	Contains considerable organic matter. Reaction may be acid or alkaline depending on the part of the process contributing the waste.	If properly neutralized, tannery wastes do not interfere materially with sludge digestion. Hair and lime residues do not digest.
Wool scouring.....	Medium...........	Has a very foul odor and contains dirt, grease, organic matter, soaps, and fiber.	When mixed with domestic sewage these wastes increase the bulk of the sludge to be digested and create masses of floating scum that do not digest readily.

Pressures likely to obtain in practical sludge digestion appear to have no effect on bacteria. There is some difference of opinion on the effect of very high pressures. Fischer states:

> "High pressure seems to be absolutely without influence upon bacteria. The processes of putrefaction and alcoholic fermentation go on without interruption under pressures of from 300 to 500 atmospheres, * * *."

Dr. F. Sierp[6] made experiments on the digestion of sludge at different depths. Samples containing one part of fresh sludge to two parts of water were placed in vessels at depths of 3.0, 1.0 and 0.15 m (9.8, 3.3 and 0.5 ft), respectively, and observed for 40 days. At the end of this period the sludge characteristics of the three samples were very similar.

Tests on the vacuum degasification of Imhoff tanks have been made by Steel and Zeller[7] at the Texas Agricultural and Mechanical College, College Station, Tex., on two Imhoff tanks treating the college sewage. The gas vents of one tank were placed under a vacuum of from 1.75 to 3.7 ft of water, generated by an automatically operated blower. Observations were made daily for five weeks of the change in H_2S, suspended matter, and bio-chemical oxygen demand of the sewage, and weekly for sixty days of the solid and ash content and the bio-chemical oxygen demand of the sludge. The authors concluded that degasification has no appreciable effect on the tank effluent nor on the digestion of the sludge.

The effect of pressure on the quantity of gas held in solution has also been considered. The quantity of gas that will be dissolved in a liquid at a given temperature is directly proportional to the absolute pressure, and where a number of gases are in contact with a liquid, the quantity of each that will dissolve is proportional to its respective partial pressure. Regardless of the pressure on the tank, however, the gas lost in the sludge supernatant will be less, in general, than 1.0% of the gas produced, provided only that the sludge supernatant is withdrawn from a point where the pressure is 18 in., or less, of water.

The effect of pressure on sludge digestion may be summarized as follows:

(1) Pressures likely to obtain in practice appear to have no effect on bacterial action causing sludge digestion.

(2) Pressures other than normal do not shorten the digestion time.

(3) Degasification under vacuum does not produce more gas nor does it have an appreciable effect on the tank effluent or on the digestion of the sludge.

(4) Pressures in the tank with reference to its effect on the quantity of gas passing into solution and drawn off in the sludge supernatant are of negligible influence.

(5) In general, depth tends to produce dense sludge, but density is not directly proportional to depth because of the influence of other factors.

MOISTURE CONTENT

There are ample data from operating sludge digestion tanks to show that the density of the sludge is greatest near the bottom of the tank as indicated on Fig. 16 and Table 16. The density of the sludge does not increase uniformly from top to bottom of the tank, and probably varies at different times at the same depth. The density of sludge as withdrawn from tanks of different depth appears to be very irregular and, within limits, a deep tank does not necessarily yield a sludge with a higher percentage of solids than does a shallow tank.

---

[6] *Technische Gemeindeblatt*, Vol. XXIX, p. 267 (1927).

[7] *Sewage Works Journal*, Vol. 2, p. 29.

Experience indicates that the moisture content of sludge has less effect upon digestion than other factors. Fisher compared rates of digestion of raw sludges containing 6, 12, and 18% solids, and concluded that within these limits there was no retardation of rate of digestion in the more concentrated sludges. There appears to be some direct correlation between moisture and content of volatile matter, with indications that activated sludge may hold greater moisture than sedimentation tank sludge, for a given volatile content.

III.—TYPES OF DIGESTION TANKS

Tanks Built of Earth.—The earliest large-scale development of separate sludge digestion tanks was at Birmingham, England, in 1912. This installation followed approximately fifty years of efforts to eliminate the odor arising from crude sewage and, later, from septic tank effluent. It included a total of fifty tanks, of which thirty were constructed of embankments of engine ash, in some cases faced with concrete paving. The remaining twenty tanks were of brick masonry.

Birmingham has a population of about 1 000 000. The dry-weather sewage flow in 1929 was 38 400 000 gal per day, of which 34 800 000 gal was treated. Digestion is carried out in two stages, sludge when partly digested being pumped from primary tanks to secondary tanks, where the process is completed. The aggregate capacity of the 50 tanks is 340 000 cu yd, individual tanks varying from 1 200 to 17 000 cu yd. The older tanks are 12 to 14 ft deep; some of the newer ones are 20 ft deep.

At several places in the United States, earth tanks or lagoons have been used for handling undigested sludge, but their operation is not, in general, analogous to that of the tanks at Birmingham. However, at Indianapolis, Ind., "deep pit digestion" has been used for both settled and activated sludge. There are seven digestion pits or lagoons about 300 ft square, diked to give a depth of 7 to 10 ft. The pit capacity may amount to 14 cu ft per capita, or more.

Open Masonry Tanks Without Mechanical Equipment.—By far the greatest number of separate digestion tanks in this country are of masonry, and it is in connection with concrete tanks that the major improvements in design and operation have been made in recent years. Concrete tanks have many advantages over the less expensive earth tanks, the most important of which are permanence, space economy, and adaptability to the requirements of operation and structural design.

The earliest concrete tanks were open at the top and had no mechanical equipment. Usually, there was no attempt to control temperature, either by insulating the tanks with earth embankments or by heating the sludge. As a result, relatively high per capita capacities were required.

The sewage works at Baltimore, Md., is the first outstanding example of separate sludge digestion in the United States. Its first unit was built in

1909–1910, and consisted of three open, rectangular tanks, each 140 ft long, 103 ft wide, and varying from 13½ to 15½ ft in depth. Additional tanks have since been installed. In 1912 there was available a digestion-tank capacity of 11.60 cu ft per capita, and in 1930, with a tributary population of 735 000, the capacity was 3.7 cu ft per capita. In that year the sewage, domestic in character, amounted to 60 650 000 gal per day.

FIG. 3.—TYPICAL INSTALLATION OF OPEN SLUDGE DIGESTION TANKS WITH ROTARY STIRRING EQUIPMENT, LAKELAND, FLA.

Concrete tanks are used for storing digested sludge with covers at Grand Rapids, Mich., and open at Peoria and Rockford, Ill. Costing roughly only one-third as much as the covered, controlled tanks in which the sludge is digested, they provide a relatively cheap storage space where sludge may be held during the winter, when the open drying beds are not in use. The storage tanks at Peoria are about 130 ft in diameter; the floors are of light concrete and the walls, lined internally with steel plate, are of 12-in. reinforced concrete, to resist earth pressure. The tanks are not heated and require no particular attention.

Open Tanks with Rotary Stirring Equipment—Experiments with mechanically cleaned digestion tanks were begun at Rochester, N. Y., in 1921. At that plant the open digestion tank was equipped with a stirring device consisting of two sets of horizontal arms attached to a central vertical shaft supported by a bridge across the tank. The lower set of arms concentrated the sludge in the bottom of the tank and gradually moved it to an outlet pipe at the center, while the upper arms prevented the formation of scum and distributed the incoming sludge over the surface.

In 1923, the first full-scale municipal plant incorporating this type of equipment was built at Brownsville, Tex. The digestion tank is circular, 35 ft in diameter, and 16 ft deep at the center. The agitator is supported from a steel superstructure spanning the tank, and consists of a gear-driven vertical shaft with two sets of arms. The top arms, constructed of steel channels, are placed just above the normal level of the liquid in the tank. Raw sludge is introduced through an inlet well mounted at the top of the shaft and flows outward along the channels, dropping into the tank through a series of holes.

Short chains, hung from the upper arms, extend into the liquid a foot or more and serve to prevent the accumulation of scum. The power unit for driving the agitator is mounted on the truss.

The success of the Brownsville unit led to the building of a number of similarly equipped open tanks in all parts of the United States (see Table 7, and Figs. 2 and 3). Since about 1925, however, this type has yielded to the mechanically equipped, covered tank.

Tanks with Fixed Covers but Without Stirring Equipment.—The desirability of controlling odors and of collecting gas has doubtless been the chief cause of the rapid adoption of covered tanks in preference to open ones, although the closed units have other advantages as well. They are markedly superior in retaining heat, and, therefore, promote bacterial activity. Furthermore, by operating with the under side of the cover under a slight pressure, scum can be kept submerged; the digestion of floating solids is thus accelerated and the formation of a sometimes troublesome thick scum layer prevented.

Among the tanks with fixed covers should be mentioned the Kremer-Kusch design, (Fig. 4) developed in Germany and in use in a number of German cities. The largest plant making use of it was built in 1920 at Hildesheim, a city of about 60 000 population. The single example in the United States was built at Palmyra, N. J., in 1922.

* Installations Nos. 1 to 13 are without cover of any kind; Installations Nos. 14 to 29 are open-type tanks, but have covers of boards laid on I-beams spanning space between superstructure and tank walls.

[a] Large capacity to handle trade wastes discharged into sewerage system.

These tanks are a development of the old Kremer sedimentation tank by the addition of a Kusch sludge cylinder below the apex of the steep hopper bottom, and a Kusch sludge digestion tank adjacent to the sedimentation tank. Sludge is transferred from the bottom of the cylinder to the digestion tanks by hydrostatic head. Two chambers are provided, rapid digestion and gasification taking place in the first, which is comparatively large and shallow. When partly digested, the sludge is removed to the second chamber, smaller in area, but deeper than the first, where the digestion process is completed.

FIG. 4.—KREMER-KUSCH SEDIMENTATION TANK WITH SEPARATE SLUDGE DIGESTION COMPARTMENT

Tark states that for a sedimentation tank 15 to 20 ft square, the usual diameter of the sludge cylinder is about 4½ ft, and that because the area of contact between the sludge in the cylinder and the sewage is small, the sludge may be retained in the cylinder for three or four days. The effect of this detention period and the depth of the cylinder is to secure a concentrated sludge with about 88% moisture.

Covered Tanks with Stirring Equipment.—Although a few covered tanks with stirring equipment are square in plan, by far the greater number are circular. The floor is cone-shaped, usually with a slope of about 1 to 48

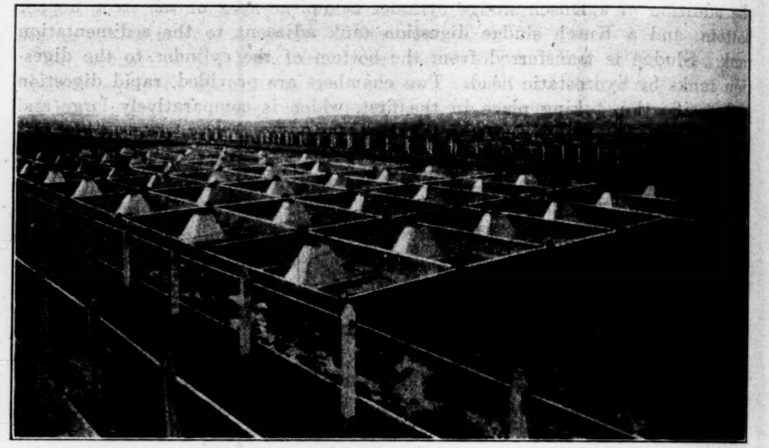

FIG. 5.—FLOATING CONCRETE COVERS ON SLUDGE TANKS, AT BIRMINGHAM, ENGLAND

FIG. 6.—TYPICAL INSTALLATION OF SLUDGE DIGESTION TANKS WITH FLOATING COVERS, AT ELYRIA, OHIO

toward a sump in the center. A pipe under the floor, terminating in the sump, permits the withdrawal of digested sludge. The roof is usually of concrete, and either slopes slightly upward toward the center or is dome-shaped. It is equipped with a gas dome, and with pipes for adding raw sludge and for carrying away the supernatant liquor. When the tank is in operation the surface of the sludge is usually up in the gas dome. The latter is equipped with a water-seal and arranged so that gas can be collected under a pressure sufficient to force it through the pipe lines and meters. The stirring device is similar, in general, to that used in the open tank. Table 8 gives data on plants using this type of equipment.

Tanks with Floating Covers.—Floating covers were first developed to permit the collection of gas at plants originally built with open tanks, but there is now at least one type of floating cover intended for use in new construction. Covers have been added to existing tanks, for example, at Plainfield, N. J., and Birmingham, England. The Plainfield covers are of wood; those at Birmingham are of concrete. The concrete covers (Fig. 5) are each 10 ft wide by 20 ft long, and are placed side by side, completely covering the tanks. At the center of each cover is a pyramidal gas dome, connected to the mains by flexible piping.

The floating cover designed for new construction is shown in Figs. 6 and 7. The framework consists of a system of radial trusses extending from

[a] Including both digestion and storage. [b] Hexagonal. [c] Industrial waste.

Multi-Stage Digestion.—Multi-stage digestion consists of a system of two or more sludge digestion tanks, each connected with the other for the progressive and automatic transfer of the sludge and gas during digestion.

The primary tank may be equipped with a fixed steel dome cover and with agitators for keeping the sludge in a homogeneous condition which is considered by some to produce digestion and gas generation at the optimum rate. The primary tank may be equipped with a hot-water heat exchanger or other equipment for heating the digesting sludge to the desired temperature. The secondary or tertiary tanks may also be equipped with steel covers designed to serve as gas-holders of varying capacities.

Settled solids from the sedimentation tank enter the first stage of digestion. This primary tank is at all times kept filled to a constant level with sludge at a proper temperature and in a homogeneous condition by the mixers. The gas produced during digestion is collected at one point on the dome roof and taken to the secondary tank for storage.

Approximately 90% of the digestion is said to be accomplished in the first stage and the sludge from the first tank is transferred to the secondary tank by hydrostatic head. In the second stage, quiescent conditions prevail which allow the solids to settle to the bottom of the tank and leave the supernatant liquor relatively clear for return to the treatment process. The settled sludge is withdrawn from the bottom for final disposal. The small quantity of gas produced in the final stages of digestion is collected in the gas-holder cover where it joins the gas produced in the primary stage.

There are at present about thirty cities in the United States that have multi-stage digestion tanks under construction.

SLUDGE PUMPING EQUIPMENT

Compressed-Air Lifts.—One of the simplest means of removing sludge from tanks is to introduce compressed air in the sludge discharge pipe. When this method is used, the sludge pipe is usually placed vertical, or nearly so, with its lower and open end near the bottom of the tank. The air pipe, perforated in its lower portion, is placed inside it.

Pneumatic Ejectors.—Although pneumatic ejectors are more commonly used for pumping sewage, they have also been installed in a number of places for pumping sludge. The body of the ejector is a cast-iron pot into which the sludge flows by gravity through a check-valve. When a predetermined

level is reached, air under pressure, from either a rotary blower or a pressure tank, enters at the top and forces the sludge through a second check-valve into the discharge pipe. Ejectors can be made to operate either automatically or manually.

Diaphragm Pumps.—These pumps are made in two different designs. The first, not generally used for pumping sludge, has a free discharge; the second, more common, is used where the sludge must be pumped against a head. The pump consists of a cast-iron pressure chamber with inlet and outlet ports and a flexible diaphragm, the periphery of which is securely fastened to the pump body. An up-and-down motion is imparted to the diaphragm, through shafting, by an electric motor or gasoline engine. The ports are usually equipped with rubber ball-valves and renewable rubber valve seats. An air-pressure chamber to smooth out the pulsations of the discharge is provided just outside the pump.

Reciprocating Pumps.—A reciprocating pump consists essentially of a cylinder equipped with a piston or plunger and suction and discharge valves. Both ball-valves and metal flap-valves are used. In order to facilitate valve cleaning, the pump-casing is usually provided with removable hand-hole

[dd] Waste gas not metered.

plates held in place by wing-bolts. Valve passages should be amply large, with as few bends as possible and free from any projections that might collect fibrous or suspended materials. Where the pump is operating against moderate or high heads, an ample air chamber should be provided in the discharge main as close to the pump as possible.

Centrifugal Pumps.—Centrifugal pumps have been widely used for handling all kinds of sludge. Single and double-suction impellers, both open and enclosed, have been tried. The best adapted to sludge pumping is probably the single-suction, enclosed impeller, secured to the end of the pump shaft. With this arrangement the sludge cannot come in contact with the shaft, whereas in double-suction pumps the shaft is in direct contact with the sludge, and stringy materials frequently wrap around it and form obstructions. The pumps should operate at speeds not greater than 800 rpm, and preferably at 720 rpm, or less, in order to reduce the wear at the inlet of the impeller. One or more easily removable hand-hole plates in the pump-casing, through which obstructions can be removed, will minimize operating difficulties. Pumps with horizontal split cases have the advantage of being easily disassembled for inspection, cleaning, or repairs.

EQUIPMENT FOR COLLECTING AND UTILIZING GAS

General.—Although gas from digesting sludge has been utilized extensively only during the past four or five years, the practice is by no means new. Perhaps the first use made of it was at Exeter, England, where, in 1895, Cameron, the Borough Engineer, collected it and burned it in a street lamp.

In 1902, James, at the leper colony at Matunga, India, constructed a gas-tight cover over two compartments of the septic tank, provided a gas-holder, and used the gas for cooking, lighting the compound, and running a ½-hp engine. The first American installation utilizing sewage gas was made in 1915 at the Peachtree Sewage Works, at Atlanta, Ga. Collectors were set in the gas vents of the Imhoff tanks, and sufficient gas was obtained to supply the plant laboratory and the dwelling of the operator.

Sludge gas is now used extensively for heating sludge tanks and buildings, and operating gas engines. Miscellaneous uses include lighting and incineration of screenings. In Germany, where it has perhaps been applied to a greater variety of purposes than elsewhere, quantities of it are frequently sold to the local gas plants. Table 10 summarizes the data on utilization obtained from a number of plants in both Germany and the United States.

EQUIPMENT FOR COLLECTION OF GAS

Gas hoods for separate digestion tanks are located above openings at high points in the roof slab. Generally, they are provided with separate water-seals, to insure against loss of gas around the hood in case the level of the liquid in the tank is lowered. Scum grids are used infrequently. In a few installations the hood consists simply of a casting tightly fastened to the roof slab without any seal.

A typical circular gas hood suitable for digesters as large as 55 ft in diameter is illustrated in Fig. 8, and Fig. 9 shows a typical rectangular hood for use on larger tanks. Data on hoods at twenty-five plants are given in Table 11.

Explosions in covered tanks containing digesting sludge are a very real hazard, but one that may be avoided if air is prevented from mixing with the gas in explosive proportions. Floating covers furnish an adequate and entirely automatic means of excluding air, since they rise and fall with the change of liquid level, and maintain a constant pressure in the dome. For tanks with fixed covers, the dome may be connected to a gas-holder, so that whenever sludge or liquor is drawn from the tank, the void will be filled by gas flowing back from the holder instead of by air entering through the water-

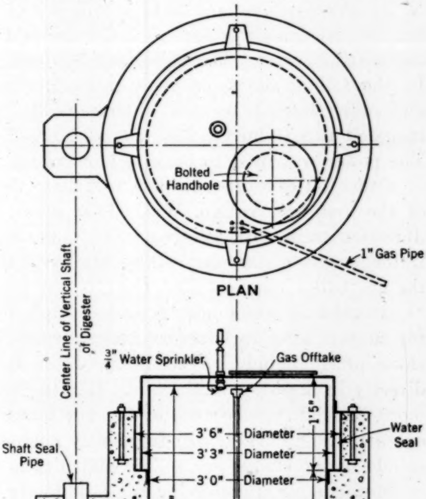

FIG. 8.—TYPICAL CIRCULAR GAS HOOD FOR SMALL DIGESTION TANKS, WITH DORR EQUIPMENT

seal. It should be noted that this method of protection fails if the gas-holder is allowed to become empty. Either the gas meters installed between dome and holder must be of a type that permits free flow of gas in both directions, or they must be equipped with a by-pass containing a check-valve.

SLUDGE-HEATING EQUIPMENT

Gas was first used for heating sludge, in February, 1926, at Plainfield, N. J. An earthen tank with a capacity of 25 000 cu ft was provided with a floating wooden cover for gas collection and a coil of iron pipe for circulating the heating water. The boiler was equipped for use of both gas and soft coal. In the fall of the same year, two additional sludge tanks were constructed and were heated by the sludge gases. The Plainfield installation also included two 15-hp gasoline engines, modified to use the sludge gas for fuel. The power was used to operate blowers for activating the sewage.

Other cities were not slow to follow the example set by Plainfield. One of the first was Antigo, Wis. That plant, built in 1927, included a covered digestion tank with heating coils, a gas boiler, a pump for circulating hot water, a gas meter, and other auxiliary devices. For a few months before the gas boiler was installed, the gas was used in a coal-burning steam heater.

At present, water heaters and steam boilers are both used to generate heat for maintaining satisfactory temperatures in sludge tanks. Boiler installations must include an auxiliary water heater, because steam is not used directly in digestion tank coils. Heating the water directly by gas is slightly more efficient, but because of the low temperature at which the water heaters operate, their burners are frequently corroded by the action of the hydrogen sulfide in the sludge gas. This difficulty is not encountered in the boilers.

Methods for transferring the heat to the sludge include:

(1) Circulation of heated water by means of a closed system through coils of pipe in the digestion tank.

(2) Discharge of heated water or heated sludge liquor directly into the contents of the tank.

(3) Pre-heating of the sludge before its discharge into the digestion tank.

(4) Circulation of sludge through a separate tank equipped with heating coils.

[a] Used for a while but found to be unsatisfactory

[b] Converted from metric units.

Digestion tanks are sometimes covered with earth to reduce heat losses; the earth should be kept dry, for it loses about one-half its efficiency if it becomes saturated. In some cases special insulating materials may be found valuable.

Any heating system requires considerable mechanical equipment and many regulating devices which need frequent checking and servicing.

Gas-Burning Power Equipment

One of the largest generating plants in the world driven by sludge gas is that at Birmingham, England. The first power unit—a 25-bhp gas engine—was installed by Mr. John D. Watson in 1921. The engine was used to operate a 5-in. centrifugal sludge pump with a capacity of 540 gal per min against a head of 36 ft. It consumed, per horse-power hour, 20 cu ft of gas, with a methane content ranging from 60 to 77 per cent. The digestion tank that furnished the gas had a sludge capacity of 2 160 cu ft.

Although the experimental unit showed several inherent weaknesses, and the rate of gas production fell short of expectations—especially during the winter—the engine worked successfully and produced sufficient power to drive the pump. As a result, a much larger engine (Fig. 10) was installed in 1927. It was rated at 150-bhp and drove a 100-kw alternator. A second engine, with an output of 400 bhp, was added in 1929, and another unit of the same size was installed a year later, making a total capacity of 950 bhp. Gas used in these engines in 1930 totaled 46 750 000 cu ft, an average of 128 000 cu ft per day.

Among sewage treatment works in the United States utilizing gas for power is the Sugar Creek Plant, at Charlotte, N. C. The installation includes two gasoline engines of standard design, except that the carburetors have been removed and a gas pipe has been attached to the intake manifold. In case it should be necessary to use gasoline, the carburetors can be re-attached in a short time. One of the units is a 75-hp, 4-cylinder engine, direct-connected to a centrifugal pump handling 3 000 gal of sewage per min, and the other is a 225-hp, 6-cylinder engine driving a centrifugal air-compressor with a capacity of 3 500 cu ft of air per min. It has been estimated that the saving in electric current would repay the cost of the two engines (approximately $10 500) in about three years. Fig. 11 shows a 300-hp engine at Peoria, Ill., operated by sludge gas.

A list of sludge gas engines and their horse-power installed in sewage treatment plants in the United States, to 1937, is as follows:[8]

Place	Horse-power	Place	Horse-power

IV.—COMPUTATIONS OF TANK CAPACITY AND HEATING REQUIREMENTS

NOTATION

The notation introduced in this report conforms essentially to the "American Tentative Standard Symbols for Heat and Thermodynamics"[9] approved by the American Standards Association in 1931.

A = area, in square feet; A_R = area of roof; A_W = area of walls; A_B = area of bottom of tank;

a_t = the fraction of volatile solids digested in time t; a_0 = the fraction of volatile solids digested in time t_0;

B = theoretical required capacity of a sludge tank, in cubic feet;

b = thickness, in inches b_R = thickness of roof; b_W = thickness of walls; b_B = thickness of the bottom of the tank;

C = calorific value of gas, in British thermal units per cubic foot;

e = percentage efficiency of utilization;

f = surface coefficient of transmittance per degree Fahrenheit; f_i = surface coefficient of heat transfer, to the inner surface of tank; f_o = surface coefficient of heat transfer from the outer surface of the tank;

g = cubic feet of gas produced per pound of volatile solids digested;

K = a ratio; K_l = ratio of the volume of liquid sludge added daily to the volume of sludge in the tank; K_v = ratio of weight of volatile solids added daily to the weight of volatile solids in the tank;

k = thermal conductance of a homogeneous material 1 in. thick, in British thermal units per square foot per hour of area, per inch of thickness, per degree (Fahrenheit) difference of temperature, between the two surfaces of the material;

N = tributary population;

Q = rate of sewage flow, in millions of gallons daily;

q = thermal transmission, in British thermal units per hour; q_R = heat transmitted through the roof; q_W = heat transmitted through walls; q_B = heat transmitted through the bottom of the tank;

S = dry solids added daily to sludge tank in parts per million of sewage;

T = temperature; T_t = temperature of the sludge in the tank; T_o = temperature of the outside air, or earth; T_s = temperature of incoming sludge;

---

[9] A.S.A. — Z10c — 1931.

t = time, in days; adopted period of digestion; t_0 = time required for substantially complete digestion (arbitrarily defined as the time required to reduce the volatile solids by 75%); t_1 = maximum interval between sludge drawings; t_2 = maximum time during which no digestion occurs;

U = over-all coefficient of heat transmittance, in British thermal units per square foot per hour, per degree (Fahrenheit) difference in temperature over-all; U_R = coefficient for heat transmittance through the roof; U_W = coefficient for heat transmittance through the walls; U_B = coefficient for heat transmittance through the bottom of the tank;

V = volatile fraction of solids;

W = weight, in pounds, of dry solids added daily;

w = percentage of water by weight; w_0 = percentage of water in entering sludge; w_1 = percentage of water in the withdrawn sludge; w_m = mean percentage of water in the sludge remaining in the tank $= \dfrac{w_0 + w_1}{2}$.

Tank Capacity Computations

General.—Capacities of from 1.5 to 3.5 cu ft per capita have been recommended, as the result of experience, for the sludge chambers of Imhoff tanks. In separate digestion tanks, however, less space is required, because the period of digestion is shortened by heating the sludge, and by thickening, agitation, or circulation. Moreover, there is no waste space such as that taken up by the sloping baffles in the lower story of the Imhoff tank. With the smaller, heated tanks, however, it must be borne in mind that the sludge must be drawn more frequently, and that the supernatant liquor is not cared for automatically.

It has been the practice to state the capacity of a sludge tank in cubic feet per capita, or cubic feet per million gallons daily of sewage. Neither of these units is altogether satisfactory, because of local differences in per capita quantities and in the strength of the sewage. The amount of solids in industrial wastes or in street wash from combined systems is a function of neither volume nor population. A better basis of design is the weight of solids in the sludge removed daily from the sewage. Consideration must also be given to the percentage of volatile matter in the solids, percentage digested, and, most important of all, the water content of the sludge.

Rational formulas have been developed for capacities of sludge tanks under several typical conditions, and diagrams have been prepared by the use of which capacities may be quickly obtained for widely varying conditions.

Case I.—Continuous Operation, with Daily Withdrawals.—Assume that a tank is in operation with a given weight of solids added daily and that an equal weight of solids disappears daily by digestion and withdrawal, so that the measurable sludge in the tank remains approximately at constant depth. Solids withdrawn include those passing out with the overflow of the supernatant liquor. The error in assuming a uniform rate of digestion from entry to withdrawal is on the side of safety.

The quantity of dry solids added on any one day will be reduced by digestion in the following period of t days by an amount, $a_t\ V\ W$ (see

Fig. 12). The average reduction in all daily additions made during the period will be $\frac{a_t V W}{2}$. The corresponding total reduction in weight will be $\frac{a_t V W t}{2}$, and the weight of solids remaining in the tank will be $W t \left(1 - \frac{a_t V}{2}\right)$.

FIG. 12

In order that the quantity of solids in the tank may remain constant, the daily withdrawals (in pounds, dry basis) must be $W \left(1 - \frac{a_t V}{2}\right)$. Obviously, the weight of solids to be provided for in the tank is equal to t times the daily withdrawals. The theoretical total weight of solids and liquid is $\frac{W t \left(1 - \frac{a_t V}{2}\right)}{1 - w_m}$ which divided by the weight of a cubic foot of liquid (62.5 ± lb) gives the minimum theoretical required tank capacity, in cubic feet:

$$B = \frac{0.008\ (2 - a_t V)\ W t}{1 - w_m} \quad \text{.....................(1)}$$

The required capacity, in cubic feet per pound of dry solids added daily, is,

$$\frac{B}{W} = \frac{0.008\ (2 - a_t V)\ t}{1 - w_m} \quad \text{.....................(2)}$$

Capacity per capita of population may be expressed either as $\frac{B}{N}$, or as $\frac{S Q t (2 - a_t V)}{15 N (1 - w_m)}$.

Example 1.—Let $a_t = 0.50$; $V = \frac{2}{3}$; $t = 30$ days; $N = 100\,000$; $W = 10\,000$; $S = 120$; $Q = 10$; and $w_m = 0.925$ per cent. Then, by Equation (1), $\frac{B}{W} = 5.33$ cu ft per lb of solids added daily; and $B = 53\,000$ cu ft (net capacity). The net capacity per capita is 0.53 cu ft. Two tanks, 40 ft in diameter and 21.2 ft deep, will give the required volume. If the depth is increased 3 ft to allow for scum and supernatant, the gross volume will be 60 800 cu ft, or 0.608 cu ft per capita.

This solution is for a controlled tank under ideal conditions. A liberal factor of safety should be applied to the theoretical quantities, because the assumed conditions in any sewage are "subject to change without notice."

Case II.—Periodic Withdrawals, Incomplete Digestion.—Assume that a tank is in operation with a given weight of solids added daily, but that the withdrawals of sludge take place at intervals of t_1 days. Further, assume that every part of the mass of sludge removed from the tank at a drawing has undergone digestion for t days. If $t + t_1$ is not greater than t_0, the conditions are as indicated in Fig. 12, in which t_1 (max.) is represented by the horizontal distance between the ordinates at x and y, in the diagram. The weight of solids removed at said withdrawal is represented by the cross-hatched area and equals $W\ t_1\left[1-\frac{a_t V}{2}\left(1+\frac{t+t_1}{t}\right)\right]$. The maximum weight of solids in the tank before drawing, is $W\,(t+t_1)\left[1-\frac{a_t V}{2}\left(\frac{t+t_1}{t}\right)\right]$.

The required volume is,

$$B = \frac{W\,(t+t_1)\left[1-\frac{a_t V}{2}\left(\frac{t+t_1}{t}\right)\right]}{62.5\,(1-w_m)} \quad \ldots\ldots\ldots\ldots\ldots(3)$$

Example 2.—Substitute the following numerical values: $W = 10\,000$; $t = 30$; $t_1 = 15$; $a_t = 0.50$; $V = \frac{2}{3}$; $w_m = 0.925$, in Equation (3); and $B = 72\,000$ cu ft, net capacity.

Again: If $t + t_1$ is greater than t_0, the conditions are as indicated in Fig. 12, in which t_1 (max.) is represented by the horizontal distance between the ordinates at x and z, in the diagram. The maximum weight of solids in the tank, before drawing is $W\left[t_0\left(1-\frac{a_0 V}{2}\right)+(t+t_1-t_0)\,(1-a_0 V)\right]$, and the required volume is:

$$B = \frac{W}{62.5}\left[\frac{t_0\left(1-\frac{a_0 V}{2}\right)}{1-w_m}+\frac{(t_1+t-t_0)\,(1-a_0 V)}{1-w_1}\right] \quad \ldots\ldots(4)$$

Example 3.—Substitute the following numerical values: $W = 10\,000$; $t = 30$; $t_1 = 30$; $t_0 = 45$; $a_0 = 0.75$; $V = \frac{2}{3}$; $w_m = 0.925$; $w_1 = 0.90$, in Equation (4); and $B = 84\,000$ cu ft, net capacity.

Case III.—Periodic Withdrawals, Complete Digestion.—The situation is shown in Fig. 12, in which t_1 is the horizontal distance between the ordinates at y and z, in the diagram. The maximum weight of solids in the tank before drawing is $W\left[t_0\left(1-\frac{a_0 V}{2}\right)+t_1\,(1-a_0 V)\right]$ and the required volume is:

$$B = \frac{W}{62.5}\left[\frac{t_o\left(1 - \frac{a_o V}{2}\right)}{1 - w_m} + \frac{t_1\,(1 - a_o V)}{1 - w_1}\right] \ldots\ldots\ldots\ldots (5)$$

Example 4.—Substitute the following numerical values: $W = 10\,000$; $a_o = 0.75$; $V = \frac{2}{3}$; $t_o = 45$; $t_1 = 15$; $w_m = 0.925$; $w_1 = 0.90$, in Equation (5); and $B = 84\,000$ cu ft, net capacity.

It is to be noted that the identical results obtained in Examples (3) and (4) indicate that, under the assumed conditions, 75%, or complete, digestion may be reached when the intervals between drawings do not exceed 15 days, whereas 30-day intervals may result in only 50% digestion.

Case IV.—Unheated Tanks in Cold Climate.—In unheated tanks in a cold climate there will be periods during which digestion practically ceases. In such cases, capacity, in addition to that computed by Equation (4), will be required. If t_2 represents this period of suspended digestion, the additional capacity will amount to $\frac{W t_2}{62.5\,(1 - w_o)}$. Adding this to the right-hand member of Equation (4), a new expression is obtained for total capacity, as follows:

$$B = \frac{W}{62.5}\left[\frac{t_o\left(1 - \frac{a_o V}{2}\right)}{1 - w_m} + \frac{(t_1 + t - t_o)\,(1 - a_o V)}{1 - w_1} + \frac{t_2}{1 - w_o}\right] \ldots (6)$$

The expression, $t_1 + t_2$, represents the maximum interval between drawings. The point where t_1 stops and t_2 begins is not sharply defined, but may be estimated, within reasonable limits, from the temperature of the sewage. Digestion may be assumed to cease when the temperature of the sludge has lowered to 50° F.

It has been observed that early drawings from Imhoff tanks, following cold weather, give sludge of greater density than is indicated by $\frac{t_2}{1 - w_o}$. This has led to the assumption that undigested sludge is densified by long storage and the volume correspondingly reduced. With increase in temperature, however, rising gas will expand the sludge mass and cause "foaming" and overflow if ample capacity is not provided.

Example 5.—Let the various numerical values be assumed as in Example 3 and let $t_2 = 60$; and $w_o = 0.95$. By substitution in Equation (6), $B = 276\,000$ cu ft.

Case V.—Tank Capacity as Determined by Permissible Ratio of Daily Additions of Volatile Solids to Volatile Solids Remaining in Tank.—Experience has demonstrated that the ratio, K_v, of volatile solids added, daily, to the volatile solids in the tank, should not exceed about 2%, for uncontrolled (unheated) tanks, nor 5%, for controlled tanks. Capacity determined by the preceding Equations (1), (3), (4), or (6), should be checked to see that it meets this requirement. If digestion is assumed as progressing at a uniform rate, the ratio of weight of solids in the tank to their volatile content, may be expressed by $\dfrac{W\left(1 - \dfrac{a_t V}{2}\right)}{W V\left(1 - \dfrac{a_t}{2}\right)} = \dfrac{2 - a_t V}{V\,(2 - a_t)}$. In order not to exceed the ratio, K_v, the volatile solids in the tank at all times must be $\dfrac{V W}{K_v}$; hence, the total solids in the tank must be $\dfrac{V W\,(2 - a_t V)}{K_v V\,(2 - a_t)} = \dfrac{W\,(2 - a_t V)}{K_v\,(2 - a_t)}$. Taking into account the water content and dividing by 62.5, the required capacity is:

$$B = \frac{0.016\ W\ (2 - a_t V)}{(1 - w_m)\ K_v\ (2 - a_t)} \qquad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (7)$$

The tank should not be drawn lower than the capacity indicated by Equation (7). Expressing the permissible quantity of influent, daily, in terms of its volumetric ratio to the quantity of sludge in the tank:

$$K_l = \frac{\text{Sludge added daily}}{\text{Sludge in the tank}} = \frac{0.016\ W}{1 - w_o} \div \frac{0.016\ W\ (2 - a_t V)}{(1 - w_m) K_v\ (2 - a_i)}$$

$$= K_v\ \frac{(1 - w_m)\ (2 - a_t)}{(1 - w_o)\ (2 - a_t\ V)} \qquad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (8)$$

Example 6.—Substituting in Equation (7), the numerical values given in Example 1, $B = \dfrac{2\,370.37}{K_v}$. For an uncontrolled tank, $B = \dfrac{2\,370.37}{0.02}$ $= 118\,500$ cu ft, and for a controlled tank, $B = \dfrac{2\,370.37}{0.05} = 47\,400$ cu ft. Substituting numerical values in the last member of Equation (8), $K_l = 1.35\ K_v$. For uncontrolled tanks, $K_l = 1.35 \times 0.02 = 0.027$; and for controlled tanks, $K_l = 1.35 \times 0.05 = 0.0675$. $\left[\text{Check: } \dfrac{0.016 \times 10\,000}{0.05 \times 47\,400} = 0.0675.\right]$

It will be noted that the foregoing value of B, for the controlled tank (47 400 cu ft) is about one-ninth less than the value obtained in Case I, in which the period of digestion is assumed at thirty days. If the method presupposed in Case I were followed, namely, daily withdrawals, the former computation would stand and the capacity would be theoretically sufficient, providing the tank was never drawn down below a capacity of 47 400 cu ft, or eight-ninths of its computed net capacity.

In Case II, Equation (3), the net capacity was computed as 72 000 cu ft. In order always to leave 47 400 cu ft in the tank, it should never be drawn lower than 47 400 ÷ 72 000 = 65.8% of its net capacity. Similarly, in Equation (4) and in Case III, the limit of draw-down would be 47 400 ÷ 84 000 = 56.4% of the net capacity.

In Case IV, the unheated tank, during the period of delayed digestion, should not be drawn below $118\,500 \div 276\,000 = 42.9\%$ of its net capacity.

It will be observed that the ratios, K_v and K_l, have two applications, useful to the plant operator: (1) The fixing of the limits of sludge withdrawal; and (2) the transformation of the ratio of volatile solids, K_v, into terms of relative volume, K_l. In the latter determination there are two principal factors which affect the value of K_l, namely, the change in water content of the sludge and the percentage reduction in volatile solids. For example, the greater the reduction of the water content, in the tank, the greater the value of K_l. On the other hand, the greater the reduction in volatile solids, the lower the value of K_l.

Fig. 13 contains five diagrams: Fig. 13 (*a*) and (*b*) refer, respectively, to heated and unheated tanks. They are plotted from Equation (8) and exhibit the relations of K_v and K_l. Fig. 13 (*c*), (*d*), and (*e*) are based, respectively, on Equations (2), (4), and (6), from which, by using the constants employed, respectively, in Examples 1, 3, and 5, the following three abridged formulas have been deduced: $\frac{B}{W} = 3.2\ (2 - a_t\, V)$; $\frac{B}{W} = 7.2 \left(\frac{5}{3} - a_0\, V\right)$; and, $\frac{B}{W} = 7.2 \left(\frac{13}{3} - a_0\, V\right)$. Fig. 13 (*c*), (*d*), and (*e*) are plotted from these formulas with "Amount of Volatile Solids" and "Amount Digested" (both expressed in percentages) as variables. In each diagram, the quantity sought may be found on the curves or may be approximated closely by interpolation. For different assumptions of the time elements and water contents, variations may be made in the constants in the abridged formulas from which different, although similar, curves will result.

HEATING COMPUTATIONS

General.—The quantity of gas produced by the digestion of sludge amounts to from 0.5 to 1.0 cu ft per capita per day, or from 5 to 19 cu ft (average, 7.8 cu ft) per lb of volatile solids added daily to the tank. A more definite unit for use in computation, however, is the amount produced per pound of volatile solids digested. The general average for this value is about 12 cu ft. Calorific values of sludge gas are discussed in Section I.

When a tank is first warmed, the temperature of the entire mass of sludge must be raised, and a relatively large amount of heat will be required; but after the operating temperature has been reached, it is only necessary to make up the losses due to conduction and radiation and to heat the relatively small quantity of incoming sludge.

Heat losses through the roof, walls, and bottom of the tank must all be taken into account. The formula commonly used for determining heat loss through a wall of homogeneous material with air or gas on one side, maintained at a given temperature, T_1, and with the other side open to the air,

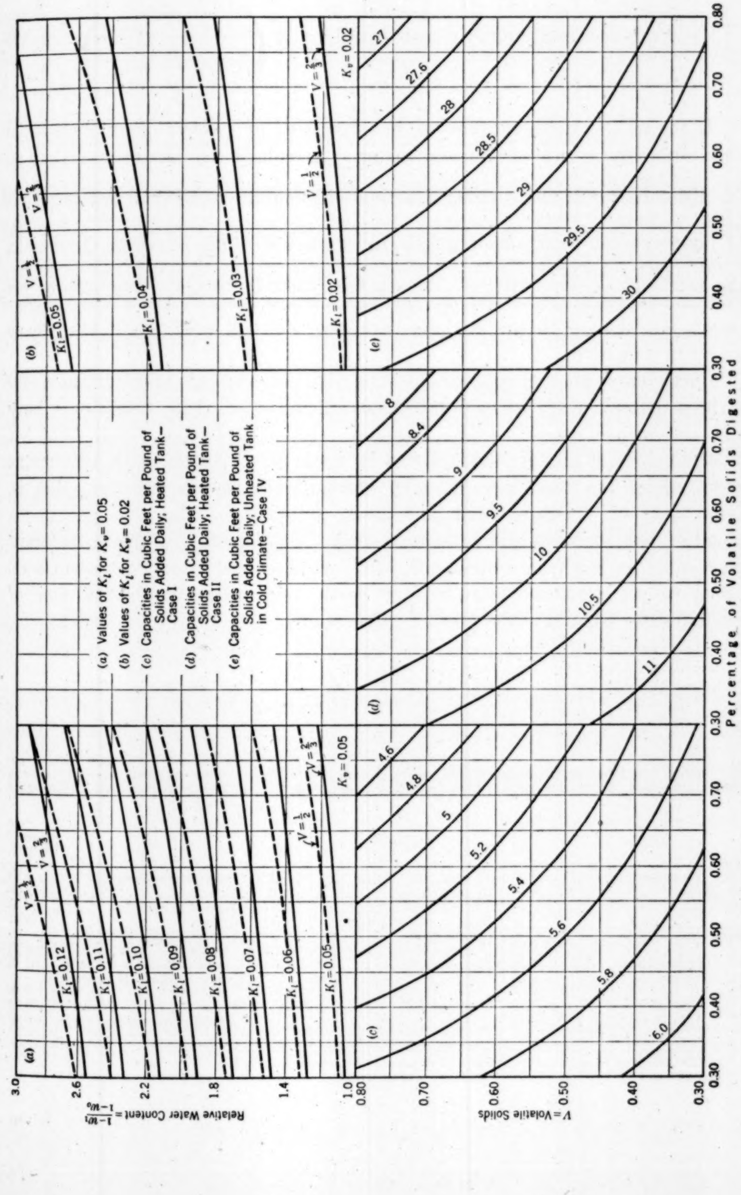

FIG. 13.—DIAGRAMS FOR DETERMINING THEORETICAL CAPACITY OF SLUDGE DIGESTION TANKS

or in contact with earth at a lower temperature, T_o, is:

$$\text{British thermal units per hour} = A\,U = A\left(\frac{T_i - T_o}{\dfrac{1}{f_i} + \dfrac{b}{k} + \dfrac{1}{f_o}}\right) \quad \ldots\ldots(9)$$

If the wall is not homogeneous, but composed of several layers of material with different values of k, each material is considered separately; that is, the denominator of the complex fraction will contain more than one term, $\frac{b}{k}$. If liquid rather than air or gas is in contact with the wall on the inside, the fraction, $\frac{1}{f_i}$, is omitted. The surface coefficients on either side of air spaces less than ½ in. in thickness are also omitted, assuming there are no convection currents.

Coefficients of thermal conductance and of surface transmittance for various materials are given[10] in Table 12. Most of these coefficients have been determined in air for heating and ventilating purposes and from hot pipes buried in the ground. There is need for experiments to determine losses under the conditions actually obtaining in sewage practice; that is, from tanks of concrete, wood, and steel, containing sludge and gas at the range of temperatures met in sewage work. Coefficients of surface transmittance into the air from hollow tile, steel, wood, concrete, and earth surfaces, losses into surrounding wet or dry earth, and losses caused by flow of ground-water, should all be given further study.

TABLE 12.—COEFFICIENTS OF THERMAL CONDUCTANCE AND SURFACE TRANSMITTANCE

(a) CONDUCTANCE THROUGH HOMOGENEOUS MATERIALS, 1 INCH THICK, IN BRITISH THERMAL UNITS PER SQUARE FOOT PER HOUR; COEFFICIENT k.				(b) TRANSMITTANCE FROM SURFACES EXPOSED TO STILL AIR*, IN BRITISH THERMAL UNITS PER SQUARE FOOT PER HOUR.	
Material	Coefficient	Material	Coefficient	Material	Coefficient*
White pine (across the grain)	0.78	Air spaces thicker than ½ in.	1.10	Smooth plaster surfaces	0.93
Virginia pine	0.96	Gypsum plaster	2.32	Concrete	1.30

		Cinder concrete	5.20		
Wood (average value)	1.00	Stone concrete	8.30	Concrete exposed to dry earth	1.00
Cellular gypsum	0.59			Concrete exposed to water or wet earth	2.00
				Hollow tile (2-in. furring)†	1.18
				Tar and gravel roofing (¾-in.)†	3.67

* For air motion at 15 miles per hr., these coefficients should be multiplied by 3.
† Over-all value for non-homogeneous combinations of materials.

Example 7.—Let $W = 4\,000$ lb; $V = \frac{2}{3}$; $a_o = 0.75$; $w_o = 0.95$; $g = 12$ cu ft; $C = 700$ Btu per cu ft; $e = 60\%$; $T_i = 82°$ F; $T_s = 56°$ F (mean annual);

---

[10] See 1931 Guide, Am. Soc. of Heating and Ventilating Engrs.

T_o in air, = 50° F (mean annual); T_o, in earth, = 60° F (mean annual) and T_o, for ground-water, = 54° F. The velocity of the air is assumed to be 15 miles per hr.

The dimensions of the digestion tank are as follows: Diameter, 40 ft; height, 24 ft, of which all but 3 ft, is banked with dry earth; roof, 8-in. concrete; walls 18-in. concrete; and floor, 12-in. concrete, located below the water-table. Gas is present between the sludge surface and the roof of the tank.

The heat available per hour is:

$$\frac{W\,V\,a_0\,g\,C\,e}{24} = \frac{4\,000 \times \frac{2}{3} \times 0.75 \times 12 \times 700 \times 0.60}{24} = 420\,000 \text{ Btu}$$

The heat required to bring the incoming sludge to the specified digestion temperature is:

$$\frac{W\,(T_t - T_s)}{24\,(1 - w_o)} = \frac{4\,000\,(82 - 56)}{24\,(1 - 0.95)} = 86\,666 \text{ Btu per hr}$$

The losses are found by substituting known values in Equation (9): $A_R\,U_R = 20\,600$ Btu per hr. and,

$$A_w\,U_w = (3 \times 40\pi\,U_1) + (21 \times 40\pi\,U_2) = 120\pi\,U_1 + 7\ U_2$$

in which U_1 refers to the part of the wall above the ground and U_2 to that below. Then,

$$A_w\,U_w = 377 \left[\frac{82 - 50}{\frac{18}{8.3} + \frac{1}{4.02}} + \frac{7\,(82 - 60)}{\frac{18}{8.3} + \frac{1}{1}} \right] = 23\,300 \text{ Btu per hr}$$

and,

$$A_r\,U_r = \frac{1\,257\,(82 - 54)}{\frac{12}{8.3} + \frac{1}{2}} = 18\,100 \text{ Btu per hr}$$

The total heat loss is $A_R\,U_R + A_W\,U_W + A_R\,U_R$, or 62 000 Btu per hr. Adding to this the amount required to heat the incoming sludge, the total heat required is found to be 148 667 Btu per hr, or 35.4% of the heat available from the gases of digestion.

These computations, it will be noted, were based on assumed mean annual temperatures for incoming sludge, air, earth, and ground-water. More heat will be required per hour in the winter, and less in the summer. A complete investigation, of course, would include computation of the requirements for both extremes

Although the cost of construction rather than the question of heat loss will usually dictate structural dimensions, it is of interest to note the effect of changes in those dimensions on the amount of heat lost. For example, a decrease of 6 in. in the thickness of the tank wall would raise the value of

A_wU_w to 28 900 Btu per hr—an increase of 24 per cent. On the other hand, if the thickness of the roof were doubled, $A_R U_R$ would become 13 380 Btu per hr, or 65% of the original value. It should be noted also that if in Example 7 the sludge had been in contact with the roof, the fraction, $\frac{1}{1.34}$, would have been omitted from the denominator in the expression for $A_R U_R$ and the heat loss would have been increased to 33 800 Btu per hr.

V.—METHODS OF SLUDGE DISPOSAL

Regardless of whether or not disposal is preceded by digestion, the problem of getting rid of sludge is an important one both to the designer and to the operator. Local conditions will determine the extent of the provisions necessary, and, together with the method of sewage treatment in use, must be taken into account in selecting the methods to be used. In general, the methods may be divided into (1) methods for disposing of liquid sludge; and (2) methods for disposing of dewatered sludge.

Liquid Sludge Disposal

The five main methods of disposing of liquid sludge are: (*a*) Transportation by scow to some suitably isolated point in deep water, in a lake, sea, or ocean; (*b*) transportation by tank wagon or truck to agricultural lands where the solid portions are eventually plowed under and become a source of plant food; (*c*) "lagooning," or intermittently flooding the sludge upon a favorably located tract of land, until deposited solids completely fill the area thus used; (*d*) broad irrigation; and (*e*), discharging into the flood waters of a stream, or by pipe line into the deep water of a lake or sea.

Method (*a*) has a limited applicability. Outstanding examples are large seaport cities. The City of London has used this method, and New York City will dispose of some undigested sludge from the Wards Island plant in this manner.

As the fertilizing value of liquid sludge is extremely small in proportion to its bulk, Method (*b*) is not promising unless local conditions are peculiarly favorable.

Method (*c*) is not final unless the deposited solids constitute a permanent fill of suitable character. The dried sludge may be hauled away by farmers for soil treatment, or by others for use on lawns, golf courses, parks, etc., so that the capacity of the lagooned area will be prolonged indefinitely Undigested sludge is lagooned in this manner at Indianapolis, Ind.

The use of Method (*d*), also, is possible in only a few localities, where the soil and the climate conditions are both favorable.

Method (*e*) has a limited application and its use is not likely to meet the approval of either laymen or public health officials.

Disposal of Dried Sludge

In a large majority of sewage works, the liquid tank sludge is dewatered before being finally disposed of. This may be done on drying beds or by several types of pressing or vacuum filtration equipment. In general, the drying beds produce a cake from 3 to 5 in. thick, and the filter presses and vacuum filtration equipment produce a cake less than 0.5 in. thick. Either cake can be transported readily.

There are six main methods of disposing of dried or partly dried sludge: (*a*) Sale or free disposal for use as fertilizer; (*b*) wasting; (*c*) use as fill; (*d*) burying; (*e*) incineration; and (*f*) transportation to sea by scow.

Method (a).—Sale or Free Disposal for Use as Fertilizer.—In the Municipal Index for 1931, twenty-seven cities and villages in the United States, representing a population of 639 000, reported that all their sewage sludge was sold as fertilizer, and thirteen additional cities, representing a population of 664 000, reported the sale of quantities varying from 10 to 95% of the total production. Data on the sale of sludge by some of these cities are given[11] in Table 13.

* Price per year. † Price per cubic yard. ‡ Price per load.

The most conspicuous example of the disposal of sewage sludge as fertilizer is Milwaukee, Wis. (not included in Table 13) where during 1928, 1929, and

---

[11] See Municipal Index, 1931.

1930, 91 800 tons of sludge (Milorganite) was sold for $1 720 000—an average price of $18.75 per ton and an average production of approximately 1.0 ton of fertilizer per million gallons of sewage treated. The Milwaukee works include grit chambers, coarse screens, fine screens, activated sludge treatment, clarification, and sludge conditioning, filtration, and drying.

The major element contributing to the value of sludge as a fertilizer is nitrogen. Schaetzle[12] reported the nitrogen content (dry-residue basis) in Baltimore, Md., sludge to be as follows:

	Percentage
Imhoff tank sludge	2.75
Digestion tank sludge	2.45
Raw sludge	2.64
Final settling basin sludge	3.19

Keefer[13] reported the results of sludge-drying at Baltimore extending over a period from August 1, 1921, to June 1, 1924, during which time 7 448 tons of wet sludge containing 68% moisture were dried to 2 949 tons of a moisture content varying from 9.4% to 23.6% and having a content of nitrogen as ammonia of from 2.05% to 2.60% on the dry basis.

In general, it may be said that the sludge produced in an activated sludge plant is considerably richer in nitrogen than that produced in clarification-sludge digestion plants. The Milwaukee sludge, for example, averaged about 6.5% nitrogen as ammonia during 1928, 1929, and 1930.

Phosphoric acid and potash are usually present in sewage sludge in small quantities (less than 1%). To the present, the relatively low market price of these ingredients has removed them from serious consideration; however, in the future, they may be of value.

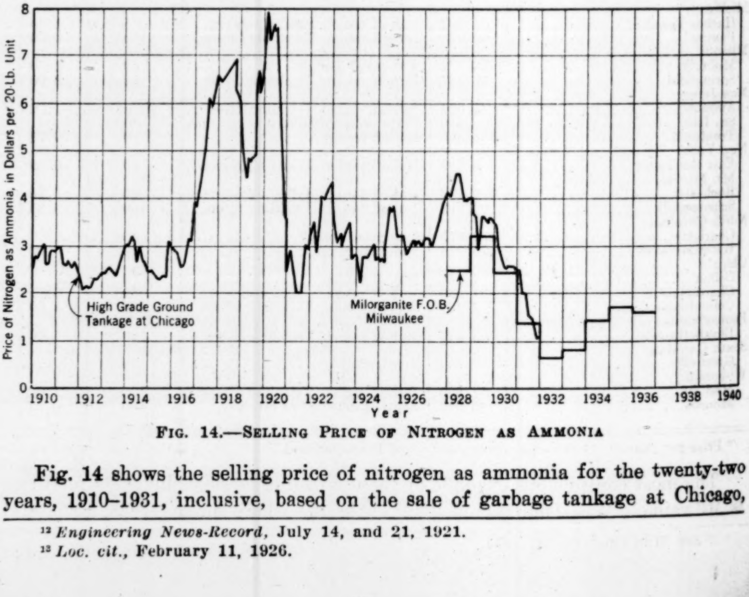

FIG. 14.—SELLING PRICE OF NITROGEN AS AMMONIA

Fig. 14 shows the selling price of nitrogen as ammonia for the twenty-two years, 1910–1931, inclusive, based on the sale of garbage tankage at Chicago,

---

[12] *Engineering News-Record*, July 14, and 21, 1921.

[13] *Loc. cit.*, February 11, 1926.

Ill., and, for the nine years, 1928 to 1936 inclusive, based on the sale of sludge (Milorganite) at Milwaukee. The higher nitrogen percentage composition of Milorganite probably enhanced its unit price and, in addition, it is probable that more of it was sold direct to ultimate users. Excess activated sludge has been dried and prepared for the market at Pasadena, Calif., and at Houston, Tex. Digested sludge from open beds has been dried and sold for fertilizer for local use at Grand Rapids, Mich., Dayton, Ohio, and Rockford, Ill. The net revenue at these plants has been relatively small but, in some years, has been sufficient to more than meet operating expenses and thus to dispose of the sludge with an income instead of an expense.

Method (b).—Wasting.—In this method the air-dried sludge is transported from the drying beds to some convenient place where it is allowed to accumulate; no plan is prepared for its ultimate disposal.

Method (c).—Use as Fill.—In this case the air-dried sludge is transported to a borrow-pit, or some other excavated area. This method of disposal is limited by the capacity of the area which can be used economically for this purpose.

Method (d).—Burying.—In this method the dried sludge is thrown into trenches and covered with earth. This method is expensive, and is warranted only where a lack of isolation makes it desirable to remove all possible source of nuisance.

Method (e).—Incineration.—The sludge is burned in specially adapted furnaces or in open piles. If air-dried sludge is properly incinerated, nothing remains but the ash, which is inert and not a source of nuisance. In some cases, the sludge from a drying bed is collected in a pile on the bed itself and burned, leaving only the ash to be removed.

Method (f).—Transportation to Sea by Scow.—This method of disposal is limited to seaport cities, and it is a question of economy as to whether the extra cost of drying and the smaller bulk to be transported is preferable to the disposal of the larger bulk of liquid sludge in the same manner.

Summary.—In many instances, it will be found that in actual practice, two or more of these methods will be in use at the same place. For example, where sludge is wasted or where it is used as fill, portions of the accumulated material may be hauled away by private individuals for use as fertilizer.

The Municipal Index for 1931 reports the methods of sludge disposal of 398 cities and villages in the United States, as follows:

(1) Sale or use as fertilizer	210
(2) Wasting	68
(3) Use as fill	38
(4) Burying	23
(5) Discharge into a body of water	18
(6) Part used as fertilizer, remainder wasted	9
(7) Part used as fertilizer, remainder used as fill	9
(8) Incineration	7
(9) Lagooning	6
(10) Transportation by scow for disposal in ocean	3

(11) Part used as fertilizer, remainder incinerated	3
(12) Broad irrigation	1
(13) Part used as fertilizer, remainder lagooned	1
(14) Part used as fertilizer, remainder buried	1
(15) Part incinerated, remainder used for fill	1
Total reporting	398

In the foregoing fifteen methods of disposal, the first five comprise 90% of the total, as indicated in the following percentage comparison:

(1) Sale or use as fertilizer	52.8
(2) Wasting	17.1
(3) Use as fill	9.5
(4) Burying	5.8
(5) Discharge into body of water	4.5
Total	89.7

It is probable that some who reported that sludge was incinerated or buried had in mind screenings instead of sludge, and that others who reported it as discharged into a body of water were confusing it with plant effluent.

VI.—OPERATING ROUTINE OF SLUDGE DIGESTION

The entire process of sludge digestion should be carried on without creating objectionable odors; should leave the solid and liquid by-products in a favorable condition for further treatment or final disposal; should provide for recovery of by-products if desirable; and, finally, should be economical and dependable.

The basic design of two-story digestion tanks has been standardized to a large extent. As a consequence, the operating technique is also more or less standard. This has not been the case with separate digestion tanks, in which variations in basic features of design, and differences in the quality of sludge handled, have resulted in a wide variety of operating practice. Some of the following statements, therefore, may be subject to considerable modification as future data are accumulated and co-ordinated.

Placing Tanks in Operation

Experience has shown that digestion tanks can be put into successful operation without the use of seeding material, but the time required for building up an alkaline sludge will undoubtedly be longer, and more careful supervision of operation may be necessary, than if the tank is seeded initially. The quantity of seeding material introduced usually ranges from 20% to 40% of the tank capacity. Seeding is especially desirable if a tank is being put into operation in the winter, although even then it is not absolutely necessary for either the two-story or the separate digestion tank.

INTRODUCTION OF SLUDGE

After tanks are in operation the problem of maintaining a proper balance between the digested, partly digested, and fresh solids, is encountered. The quantity of seeding material in the digestion compartment should always be sufficient to counterbalance the acid produced by the incoming fresh solids. It is advisable to add fresh solids continuously, or at frequent intervals, and at rates not exceeding 3% to 5% of the solids in the tank. This proportion should probably be based upon volatile matter content rather than on a total solids basis (see Section IV).

USE OF LIME

The optimum pH-value, or reaction, for any particular plant must be determined by experimentation. Reaction control should not be necessary if the tanks are properly operated, although it may be necessary in cases where the unusual character of sewage or improper operation of tanks has destroyed the alkaline balance of the sludge.

The re-agent generally used in reaction control is lime hydrate, which not only increases alkalinity, but also coagulates the colloidal organic matter. The results obtained depend to a large extent upon the quantities of re-agent added, and the method of application or mixing.

STIRRING OF SLUDGE

There is considerable difference of opinion as to the advantages of stirring sludge. It does seem necessary or desirable, however, that some stirring be done, at least during intervals when raw sludge is being introduced into the tank. The amount of stirring that should accompany this process remains open to question. There is apparently little necessity for stirring in a 2-story tank, although some agitation may be necessary when sludge is being withdrawn. Stirring in separate digestion tanks has been practiced to varying degrees in many installations. The advantages usually claimed are that it sets free the entrained gas at a uniform rate, and promotes digestion by helping to maintain a favorable reaction, mixing any chemical re-agents that may be added, and assisting in distributing raw sludge through the tank.

COLLECTION, MEASUREMENT, AND STORAGE OF GAS

The operation of this phase of the sludge digestion process may be summarized, as follows:

1.—Individual and master meter readings should be recorded daily. Meters should be checked occasionally for accuracy.

2.—Gas lines, domes, etc., should be checked frequently and kept clear and free from obstructions at all times. Usually, ample sizes of pipes will insure against troubles of this nature.

3.—Pressures in the system should be checked and recorded daily, or more often.

4.—Water in seals should be maintained at proper levels, and kept clear of sludge and scum. Outside seals should be filled with oil or similar material during winter months to prevent freezing.

5.—Lights and fires should be kept away from digestion tanks and from the gas-collection system.

6.—Gas masks should be kept available for use in case of emergency.

REMOVAL OF SLUDGE

The removal of sludge depends upon the degree of digestion attained. In unheated tanks it is advisable to hold sludge in the tanks as long as possible in the spring in order to take care of the winter accumulation of partly digested sludge.

In the process of drawing, the sludge should be allowed to flow at a slow regular rate, in order to prevent the formation of channels and the withdrawal of partly digested sludge. Failure of sludge to flow may usually be remedied by agitation with water-jets, or by mechanical means.

REMOVAL OF SCUM

The accumulation of large quantities of scum, which consists of fibrous material, such as leaves, sticks, matches, and seeds, in the gas vents of 2-story tanks, or on the surface of separate digestion tanks, may cause odors, prevent the even and free discharge of gas, or clog the pipe lines. Heavy layers of scum may form only during the first few months of operation, or may persist for long periods without necessarily causing a reduction in tank efficiency.

When necessary, various methods are used for preventing excessive formations of scum, such as the installation of submerging racks, or the mechanical breaking up of the layer by hand or by stirring equipment with revolving arms, thus causing the scum to re-settle. In some cases, it has been found successful to flush with water or sludge liquor so that the liquid scum can be drawn off through pipe lines. Ordinarily, it will be necessary to remove scum only once or twice a year, if at all.

REMOVAL OF SUPERNATANT SLUDGE LIQUOR

The satisfactory disposal of the supernatant liquor which separates from the solids in separate digestion tanks, presents a difficult problem. This liquor is never clear, has a high oxygen demand, and is relatively high both in suspended and dissolved solids.

Draw-off lines for supernatant sludge liquor should be provided at different elevations in the tank. The various methods of disposing of the liquor include its return to the inlet of sedimentation tanks or to the digestion compartment of 2-story tanks, or its discharge to drying beds.

CONTROL OF FOAMING

The term, "foaming", is applied to a condition which may exist in either a 2-story tank, or a separate digestion tank, when large quantities of light, gas-lifted sludge rise in the gas vents or to the surface of the tanks. This condition is not only unsightly in appearance and productive of foul odors, but it interferes seriously with the efficiency of the plant.

Various methods have been suggested for the control of foaming, such as (*a*) drawing sludge; (*b*) hosing gas-vent areas by water under pressure; (*c*) resting the tank by putting it out of service; (*d*) circulation of supernatant liquor on to the surface of the material; (*e*) adding hydrated lime either to the raw sewage or, preferably, to sludge as it is pumped back into the gas vents; (*f*) treatment of the raw sewage with chlorine; and (*g*) the removal of all the sludge from the tank and the building up of a new sludge. The accepted practice seems to be the withdrawal of sludge from the tank and the maintenance of proper quantities of good seeding material.

CONTROL OF ODORS

The entire elimination of odors about a sewage treatment plant is impossible, but a thorough knowledge of the treatment processes and careful operation of the plant will usually make it possible to avoid odors about which justifiable complaint could be made. It is more effective to avoid conditions that produce odors than to control the odors themselves.

One of the most important single factors having a direct bearing upon the control of odors is that of general cleanliness. All accumulations of sewage solids and grease on the walks or walls of the tanks, or about the grounds, should be removed immediately. Except for well-digested sludge drawn upon the beds, or otherwise disposed of, no sludge should be left exposed to the atmosphere. The hydrogen sulfide odors which sometimes develop in sedimentation and sludge digestion tanks may be controlled rather effectively by the use of liquid chlorine.

TOOLS REQUIRED IN ROUTINE OPERATION

General Tools.—These include tools that may be used elsewhere about the plant, such as wheel-barrows, shovels, hoes, brooms, ladders, and valve keys.

Special Tools.—Tools required for 2-story or separate sludge digestion tanks include water hose and nozzle for flushing, rubber squeegees, or chain drag, for cleaning flow compartment walls, perforated metal or wire skimmer for removal of scum, pitcher pump and hose for determining sludge level, and sampling buckets for composite samples, and long-handled dippers for securing the small amounts.

ANALYSES AND RECORDS

Laboratory control and the keeping of records of laboratory analyses are important as a guide to proper operation. The records of solids introduced and removed from tanks are important because the efficiency of digestion processes is largely measured by the reduction of volatile water. Gas quantities and temperature records are important in studying rates and progress of digestion.

Every care should be taken to have the results of the analyses represent a true portrayal of what has been accomplished during the process of changing (fresh) solids to digested sludge[14]. Data that should be obtained in connection with sludge digestion tanks may be summarized as follows:

(1) General Data (recorded daily): Temperature of atmosphere, in degrees Fahrenheit; hot water circulated, in gallons per day; temperature of circulating water (incoming and outgoing); and temperature of sludge in tank.

(2) Incoming Sludge: Time of introducing sludge, in hours; volume added, in gallons; temperature of sludge, in degrees Fahrenheit; and analysis of sludge, daily, or for each volume added: (*a*) Percentage of total and dissolved solids; (*b*) percentage of ash and volatile matter; (*c*) pH-value and alkalinity; and (*d*) specific gravity or actual weight per gallon.

(3) Sludge Withdrawn: Volume withdrawn, in gallons; and analysis of sludge, daily[14] or for each volume withdrawn (same as for incoming sludge).

(4) Supernatant Sludge Liquor: Volume withdrawn, in gallons; analysis of supernatant, daily[15], or for each volume withdrawn: (*a*) Percentage of total and dissolved solids; (*b*) percentage of ash and volatile matter; and (*c*) pH-value and alkalinity.

(5) Scum (Recorded Monthly): Thickness, in inches; volume removed, in gallons; analysis of scum: (*a*) Percentage of moisture; (*b*) percentage of ash and volatile matter; (*c*) pH-value and alkalinity; and (*d*) specific gravity.

(6) Gas: Volume, in cubic feet (recorded daily); analysis of gas (weekly): (*a*) Heat value, in British thermal units; and (*b*) percentage of CO_2, N_2, CH_4, O_2, and H_2.

In sampling digested sludge, composite samples should be collected proportionate to the quantity of sludge pumped. The fresh solids should be sampled by suspending small buckets in the flow compartments of sedimentation tanks.

Analyses of sludge removed from primary settling tanks and sludge digestion tanks should include observations as to color, odor, and streaking on a glass plate; and determination of volume, percentage of moisture, percentage of volatile matter, pH-value, alkalinity, specific gravity, and occasionally grease and total nitrogen, and possibly bio-chemical oxygen demand.

It is of great importance, in the operation of digestion tanks of both types, to measure and record the depth of sludge in the tank, as well as the quantities added and removed. In the case of a 2-story tank, the information is important in order to keep the sludge line well below the slot.

Sludge may be measured with any of the following types of equipment:

1.—Pitcher pump with flexible hose. The suction end of the hose can be raised or lowered until the sludge line is found.

2.—Flat tray of fine wire mesh or perforated plate, attached to a chain.

3.—Bottles (with removable stoppers) which can be lowered by means of a pole to obtain samples at various depths.

All of the aforementioned methods are fairly reliable, but the pitcher pump and hose is the equipment most widely used.

Division on Sludge Digestion

APPENDIX I

OPERATING DATA FROM GRAND RAPIDS, MICHIGAN, APRIL, 1931, THROUGH JUNE, 1932

Through the courtesy of the City Officials at Grand Rapids, Mich., and of James R. Rumsey, M. Am. Soc. C. E., Superintendent of the Sewage Treatment Works, and N. G. Damoose, Chemist, the Committee was given the opportunity of making observations and collecting specific information relating to the operation of the sludge digestion tanks at Grand Rapids, from April 1, 1931, through June, 1932.

The sewage treatment plant at Grand Rapids comprises screening, sedimentation, and separate sludge digestion, and includes square settling tanks and traction-type equipment for removing sludge. There are four sludge digestion tanks and two sludge storage tanks. The digestion tanks are 70 ft in diameter and 24.5 ft deep (liquid side depth), and are equipped with tight covers, stirring devices, and heating coils. Three pumps are provided for handling raw sludge and two for digested sludge. Interconnections permit its transfer from one tank to another, although during the observation period there was practically no re-circulation of sludge between the tanks, and no seeding.

The rated capacity of the plant is 32.5 mgd, and the average flow during the period of observation was 24.4 mgd. Thus, the digestion tanks were not heavily loaded. The estimated connected population upon which all the following per capita computations are based is 168 000. The population equivalent, based on a 5-day bio-chemical oxygen demand of 0.168 lb per capita, is 180 000.

The City of Grand Rapids has a combined sewerage system. The sewage is relatively fresh, and the average flow is about 140 gal per capita per day. Although there are no unusual industrial sewages tributary to the treatment plant, the per capita quantity of suspended matter is relatively high, amounting to 0.230 lb per capita per day. A summary of typical analyses for the observation period is given in Table 14.

OPERATING ROUTINE

The sludge-collecting equipment in the primary settling tanks is operated continuously. At 8-hr intervals the valves on the sludge lines are opened and fresh sludge is pumped to each digestion tank, for a period of 10 to 30 min. This routine of operation results in fresh sludge with an average solids content of 4.9 per cent.

Space for the incoming sludge was made available either by the discharge of sludge supernatant, or by the withdrawal of digested sludge. The ordinary routine was to allow sludge supernatant to flow from the digestion tanks whenever fresh sludge was introduced, but to withdraw digested sludge only once in 24 hr. The supernatant was returned to the inlet of the primary settling tanks. There was no difficulty in maintaining a practically uniform temperature in the digestion tanks, the departure from the average during the delivery of sludge being negligible.

There is a sampling cock on the discharge of each of the five pumps. During pumping, a 1.5-pt sample was taken every 10 min and composited. The length of the pumping period was determined by the thinning of sludge at the sampling cock.

To facilitate uniform operation, a ratio of sludge withdrawn to sludge introduced was determined from time to time, in order to maintain the proper sludge depth in the tanks. Ratios ranging from 17.5% to 50% were applied.

DATA SECURED

During the period of observation, an effort was made to secure a complete record of the operation and behavior of the sludge digestion tanks. All the necessary analyses relating to incoming sludge, withdrawn sludge, sludge supernatant, scum, and gas were included and were made by the Laboratory Staff of the Grand Rapids treatment works on daily composites with few omissions. In addition, several sets of determinations were made to ascertain the characteristics of the sludge at depth intervals of 5 ft. It was impossible to get more than a few analyses of the scum and the sludge supernatant.

The data were averaged from daily analyses. A summary is given in Table 15. The percentage of volatile matter and of solids in the fresh and withdrawn sludges for each of the four tanks is shown on Fig. 15.

The sampling and analysis of sludge are subject to some error and, therefore, the results cannot be considered as precise. As a measure of accuracy, a computation of a solids balance was made.

All determinations of the solids content of sludge were made by evaporation, and the results, therefore, are in total solids rather than in suspended solids. The difference between the two is only a matter of 2% or 3%, depending upon the moisture content of the sludge.

For the computation of the solids balance, a period between June 15, 1931, and May 31, 1932, was taken, as these were the first and last dates on which analyses were made of the total solids content of the digestion tanks.

During the observation period there was but one unusual condition of any importance. Difficulty has been experienced in Grand Rapids with the dis-

‖Assuming 65 lb. per 1 000 cu. ft.

posal of lime sludge from the water-softening plant. During April and August, 1931, some of it was discharged into the sewers. This sludge was almost entirely calcium carbonate, with a small quantity of magnesium hydrate. It had no caustic alkalinity. About 44% of the sludge was volatile. During the first period, the dry weight of lime sludge was about three times, and during the second period, about twice, the dry weight of suspended sewage solids. After the first period (ending on April 13, 1931) it required 36 days for the lime to work out of the plant. After the second period (ending on September 3, 1931) practically all the lime added during August had disappeared from the raw sludge by September 4.

Condition of Sludge in Tanks

Fig. 16 shows the percentage of solids in the sludge in each of the four tanks at various depths on the days when samples were taken and analyzed.

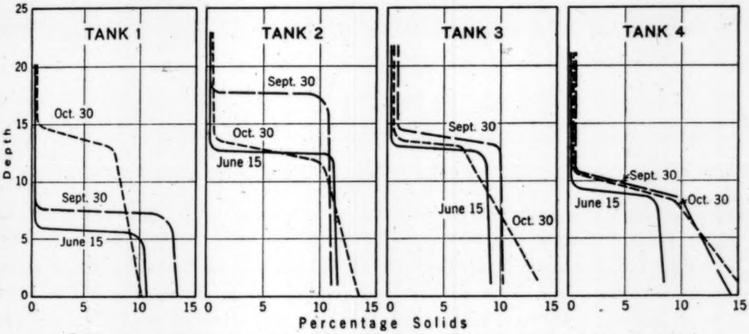

Fig. 16.—Percentage of Solids in Digestion Tanks at Grand Rapids, Mich.

The average percentage of solids for all four tanks was 4.7. The reason for this abnormally low value is that the sludge line itself was low—about at mid-depth in each tank. As indicated in Fig. 16, the tanks were nearly half full of sludge so that the average moisture content was abnormally high. This line was relatively definite, and the average percentage of solids below it, for the four tanks, was 8.9. The average solids content of the sludge as withdrawn, was 12.9.

There was not much variation in the pH-value between the top and bottom of the tanks, the change in general being from 7.0 at the top to 7.6 at and near the bottom. The volatile content of the tank solids decreased appreciably from top to bottom, as shown in Table 16.

Sludge Supernatant

The quantity of sludge supernatant was determined by computing the difference between the quantity of fresh sludge and the quantity withdrawn, as obtained from Venturi meter readings.

In general, the supernatant carried from 2 700 to 5 000 ppm of total suspended solids. The solids discharged from the tanks in sludge supernatant

* Empty

for the entire period of observation amounted to about 5.8% of the total solids pumped into the tanks during the same period.

SCUM

There was a typical, black, somewhat fibrous scum, relatively thick, under the roof of each digestion tank during the observation period. The scum varied in thickness up to a maximum of about 3 ft. It gave no trouble, and no effort was made to remove it or to break it up. Moisture content and other pertinent data are given in Table 17. When two of the tanks were emptied (in January and May, 1932), it was found that the scum layer, upon reaching the bottom of the tank, could not be pumped out even after strong hosing. It was 1.5 to 2.0 ft thick and was of a heavy clay-like consistency matted with hair and sticks.

Gas Production

The metered quantities of gas are considered to be somewhat lower than the amount actually produced, because of occasional blowing of the gas seals and some clogging of the lines. The seals have recently been increased in depth, and changes have been made in the domes to eliminate some of these difficulties. Subsequent meter records indicate somewhat higher rates of production. For the purposes of this study, however, the records as obtained have been used—proper consideration, of course, being given to barometric pressure, moisture, and temperature. The quantitative results are shown in Table 15, and the composition and calorific value as indicated by various analyses throughout the period are shown in Table 19.

This gas has been used in the boilers for digestion-tank heating, without any difficulty, and in the laboratory, and for general heating about the plant.

Solids Balance

The data for the computation of solids balance were taken between June 16, 1931, and May 31, 1932, as these are the first and last dates on which analyses were made giving the total solids content of the digestion tanks. A summary of the solids balance follows:

(*A*)	Total weight of solids in digestion tanks on June 16, 1931 (as computed from the data in Fig. 15), in pounds	1 010 000
	Total solids introduced as fresh sludge from the primary settling tanks between June 16, 1931, and May 31, 1932, in pounds	7 895 000
	Total solids to be accounted for, in pounds	8 905 000
(*B*)	Total weight of solids in digestion tanks on June 1, 1932 (as computed from the data in Fig 15), in pounds	1 302 000
	Total solids removed from digestion tanks as sludge, in pounds	4 570 000
	Total solids withdrawn from tanks with sludge supernatant, in pounds	418 000
	Equivalent weight of gas as reported by the gas meters with a correction of 1.0% added for gas lost through water-seals (and representing the weight of solids volatilized), in pounds	2 944 000
	Total weight of solids accounted for, in pounds	9 234 000

In the foregoing list, the solids accounted for are greater than those to be accounted for, by 329 000 lb, or approximately 3.7 per cent. This is a close balance, considering the difficulties of sampling, of measuring sludge in meters, and of determining the percentage of volatile matter and the specific gravity of the sludge.

Computed Digestion Time

A digestion time was computed as the displacement period of solids withdrawn, by dividing the total weight of solids in all four tanks by the daily weight of all solids removed therefrom, whether as sludge, as sludge supernatant, or as gas. Table 20 gives these quantities and the displacement periods.

TABLE 20.—COMPUTATION OF DIGESTION TIME

Date of analysis	Weight of dry solids in four tanks, in pounds	Weight of dry solids removed per day*, in pounds	Displacement period, in days
1931:			
June 15	1 010 000	16 500	61
October 30	1 363 000	28 100	49
1932:			
March 1	701 000	14 900	47
May 4	863 000	16 100	54

* Average for the two months following the date of analysis of tank content.

All the sludge was well digested, the volatile matter being consistently less than 50 per cent. The time used for digestion, as indicated by these observations, is not more than 50 days and may be somewhat less.

APPENDIX II

OPERATING DATA FROM ELYRIA, OHIO, APRIL 1, 1931, THROUGH SEPTEMBER 30, 1932

For an 18-month period extending from April 1, 1931, to September 30, 1932, arrangements similar to those described in Appendix I were made for collecting information relative to the operation of separate sludge digestion tanks at Elyria, Ohio. The opportunity was afforded through the courtesy of the Hon. James A. Hewitt, Mayor, and the Hon. J. N. Eidt, Safety-Service Director, and the work was done through the faithful co-operation of James R. Collier, Superintendent and Chemist at the sewage treatment works.

The sewage works at Elyria consists of bar gratings, grit chambers, preliminary sedimentation tanks of the 2-story type, aeration tanks, activated-sludge settling tanks, separate sludge digestion tanks, and covered sludge-drying beds.

The two 2-story tanks, each 62 ft in length, 31½ ft in width, and with a water depth of 27 ft, provide a normal detention period in the sedimentation compartment of 60 min. They are equipped for gas collection.

There are two separate sludge-digestion tanks, each 50 ft in diameter, with conical bottoms, the total water depth being 34 ft, measured from the wall coping. Both tanks are equipped with floating covers with provision for gas collection. Each tank is heated by water circulated by a centrifugal pump through galvanized iron pipe, hung around the circumference of the tank 18 ft below its coping. A continuous record of the temperature of incoming and outgoing heating water is kept by recording thermometers. Sludge temperatures are measured, as desired, by thermometers suspended in the sludge. All gas is metered and two gas boilers are provided for heating the water used in the circulating system.

Between the two digestion tanks are a sludge-mixing and control chamber and a room housing the water-seals, a master gas meter, sludge-control valves, and an automatic gas-pressure regulator and excess gas escape. There is no provision for gas storage except in the digestion tank. Sludge is transferred from the activated-sludge settling tanks by gravity, and may be discharged either to the separate digestion tanks, the sludge-drying beds, or to the sludge suction well (whence it can be returned to the primary tanks, or to the digenstion tanks). Sludge mixing may be accomplished in the digestion tanks by drawing off at the bottom and pumping back to the top of the tank.

Sludge supernatant from each tank can be drawn off at either of two elevations and discharged directly to the sludge-drying beds, or pumped to the sewage as it enters the 2-story tanks, or to the sludge compartments of the 2-story tanks.

The plant is designed to serve a population of 36 000, with an average sewage flow of 100 gal per capita daily, although the estimated connected population at the time of the observations was 21 000. The design capacity was based upon a 60-day period of digestion, with heating for maintaining a temperature of 77° F.

The sewerage system, with the exception of that serving the older and more densely populated section of the city lying between the east and west forks of the Black River, is of the separate type. The sewage is relatively fresh and of normal strength, although there is a small percentage of pickling liquor wastes. The average volatile content of the suspended solids in the crude sewage is 64.2% and the percentage of volatile matter in the partly digested 2-story tank sludge introduced into the sludge-digestion tanks is 61.7 per cent. Summaries of sewage analyses and of the characteristics of the sludge removed from the 2-story tanks are contained in Tables 21 and 22.

OPERATING ROUTINE

The 2-story settling tanks are operated in parallel and the direction of flow is reversed regularly at the beginning of each month. Scum is drawn from beneath the gas-collection domes not oftener than twice each month.

TABLE 23.—SUMMARY OF DATA COLLECTED AT ELYRIA, OHIO, SEWAGE TREATMENT PLANT

Sludge removed from the activated sludge-settling tanks is introduced continuously into the incoming sewage at the entrance to the 2-story tanks.

Once each week sludge supernatant is drawn from the separate digestion tanks and discharged into the sludge compartments of the 2-story tanks at points just above the top of the hoppers. Following the supernatant draw-off, if desired, ripe sludge is applied to the sludge-drying beds, and regularly each week, a charge of primary tank sludge is admitted to each digestion tank. After this, if mixing is desired, it is accomplished by drawing ripe sludge from the bottom of the tanks and pumping it into the fresh solids which have been charged at the top.

The total solids content of the digested sludge during the 18-month period of observation averaged only 5.3 per cent. This could undoubtedly be increased by a longer detention period in the digestion tanks, but due to the demand for dried sludge (which is sold at a fixed price per bed), sludge was withdrawn as soon as it was satisfactory for drying.

DATA SECURED

A summary of the data collected during the 18-month period of observation is given in Table 23.

Measurements of sludge added to, and removed from, the digestion tanks were made by noting the actual displacement in the tanks. The volume of sludge removed was also checked by observations of wet sludge applied to the sludge-drying beds.

SLUDGE SUPERNATANT

The sludge supernatant from the digestion tanks contained from slightly less than 5 000 to 33 000 ppm of total solids, with a volatile matter content of 47.5 per cent. The total solids discharged in the sludge supernatant amounted to about 21% of the total solids admitted to the digestion tanks.

Analyses of the supernatant were made at frequent intervals, with results shown in Table 24.

GAS

The gas from the separate sludge digestion tanks, as well as that collected from the gas vents of the 2-story tanks, is metered through separate gas meters and is used for heating the water circulated in the digestion tanks. At present, all excess gas is burned and wasted. During the first part of the period considerable gas escaped through the water-seals before the covers had been finally adjusted to maintain a level position. It is estimated that the loss amounted to at least 10% of the total volume metered, and, therefore, the quantities have been corrected to include this allowance. (In addition, a quantity of gas amounting to about 10% of these volumes was collected from the primary settling tanks.) The characteristics of the gas are shown in Table 25.

The number of cubic feet of gas per pound of incoming volatile matter was undoubtedly lower than could have been obtained, as sludge was drawn to the drying beds sooner than would be the case ordinarily. The gas has an average calorific value of about 750 Btu per cu ft, and burns readily under the boilers. No trouble has been experienced with clogging of the gas lines and the discharge of gas has been fairly uniform.

SCUM

No attempt was made during the period of observation to remove or to break up the layer of scum in the digestion tanks. The thickness of the layer

....	...	....	....	...
....	...	....	....	...
....	...	....	....	...

varied from 10 in. to a maximum of 24 in. An average of several analyses showed it to have the following characteristics:

Moisture content	86.4%
Ash content	34.2%
Volatile matter	65.8%
pH-value	6.9%
Ether soluble (dry solids)..................	27.2%

TEMPERATURE

The temperature of the sludge in the digestion tank was maintained at an average of 78° F, and varied from a minimum of 74° to a maximum of 82 degrees. The average temperatures of the incoming and outgoing circulating water were 107° and 96° F, respectively.

SOLIDS BALANCE

No determination of the total solids content of the tanks was made at the end of the period of observation; hence, the solids balance can only show the difference between total incoming and discharged solids for the 18-month period. This computation is as follows:

Total weight of solids added to tanks........		1 808 433
Total weight of solids removed as sludge	438 231	
Total weight of solids withdrawn with supernatant	386 064	
Equivalent weight of gas, including allowance for loss..........	394 019	1 218 314
Solids unaccounted for....................		590 119

The solids unaccounted for, without adjustment for a possible difference in the amounts of solids in the tanks at the beginning and at the end of the test period, amount to 32.6% of the total solids added to the tanks. Undoubtedly, a large part of this unaccounted for loss is attributable to liquefaction during digestion.

PERIOD OF DIGESTION

If it is assumed that the period of digestion is represented by the actual time of displacement of the sludge in the digestion tanks, the average number of days required for digestion during the period of observation at Elyria would be: $548 \div \frac{5\,293\,422}{2\,(300\,540)} = 62.$

It will be noted that the volatile matter in the sludge removed from the digestion tanks was at all times less than 50 per cent. The sludge was odorless, of good quality, and thoroughly satisfactory for drying and final disposal.

MEMOIRS OF DECEASED MEMBERS

GEORGE HERNDON PEGRAM, Past-President and Hon. M. Am. Soc. C. E.[1]

Died December 23, 1937

George Herndon Pegram was born in Council Bluffs, Iowa, on December 29, 1855. His father, Benjamin Rush Pegram, son of Dr. John Coleman Pegram and Caroline Pegram, was born in Petersburg, Va., on April 28, 1828; and his mother, Mercy Adelaide Robbins, daughter of Abner Robbins and Eunice (Sears) Robbins, was born in Brewster, Mass., on September 5, 1828. The Pegrams of Virginia and the Sears of Massachusetts have long been prominent families of their respective sections of the country.

Mr. Pegram's father owned a bank and a store in Council Bluffs and a store in Denver, Colo., and also was engaged in freighting across the plains. At the time Mr. Pegram was born, Council Bluffs was a town in Indian country, crudely built, most of the houses being of wood with a few of brick. It was the headquarters of the Pottawottomies. Mr. Pegram's birthplace was a log house, one of the best of its time. The late General Grenville M. Dodge, Hon. M. Am. Soc. C. E., the noted railway builder, was a partner of Mr. Pegram's father from 1857 to 1861, when the Civil War broke out. Soon after the Pegrams moved to St. Louis, Mo., where the senior Pegram joined his brother in steam-boating on the Mississippi River. At one time they owned and operated six river steamers, some being the finest in service at that time.

Young George entered school when he was seven years old, but within a month suffered a severe attack of typhoid fever, and it was six months before he was strong enough to walk. In 1864, the family moved to New Orleans, La., where they remained for two years, returning to St. Louis in 1866.

The long convalescence from typhoid fever and the frequent changes in residence seriously retarded George Pegram's education, and he has stated that his progress was slow " because I could not seem to learn." In the fall of 1866, when he was eleven years old, he entered the lowest grade in the preparatory school of Washington University, at St. Louis, and finished his course in one year less than the scheduled time. His comment on this was, " I learned to work." He then entered the Polytechnic Department of Washington University and was graduated in 1877 with the degree of Civil Engineer. At the graduation exercises, Dr. Eliot, the Chancellor, remarked that Mr. Pegram had sustained the highest standard of any graduate.

Business was bad in 1877, and it was difficult to find a position; however, before the end of the year Mr. Pegram joined a survey party on the location of an extension of the Utah and Northern Railroad, from Franklin, Idaho, north through country in which war with the Nez Percez Indians was raging. The party was protected by a detachment of soldiers but no trouble occurred with the hostile Indians. This work was suspended at the end of the year.

---

[1] Memoir prepared by a Committee appointed by the Board of Direction of the Society, consisting of Richard S. Buck, *Chairman*, F. W. Gardiner, and O. E. Hovey, Members, Am. Soc. C. E., and Arthur S. Tuttle, Past-President, Am. Soc. C. E.

In March, 1878, Mr. Pegram joined the staff of the late Colonel Charles Shaler Smith, M. Am. Soc. C. E., in St. Louis. Colonel Smith was a man of unusual ability, character, and personality, and one of the greatest bridge engineers developed in the United States up to that time. Association with him was a great privilege of which Mr. Pegram took full advantage. He remained with Colonel Smith until May, 1880, except for a period of six months when he was engaged in mercantile business in Leadville, Colo.

In May, 1880, Mr. Pegram was recommended by Colonel Smith to the position of Chief Engineer of the Edge Moor Iron Company, near Wilmington, Del. He was engaged shortly after and remained in that capacity until he resigned in 1886. His organization of the Engineering and Drafting Departments at Edge Moor was so excellent that it soon became recognized that service there constituted the best post-graduate course available to young men who wanted to follow Bridge and Structural Engineering. Edge Moor was the leader in the progressive development of the best shop equipment and practice, and fully one-half the Office Staff was made up of engineer graduates anxious to learn the best in preparation for an engineering career. Many well-known bridge and structural engineers acquired their first practical experience at Edge Moor under Mr. Pegram and his able successors.

Mr. Pegram had early decided that at thirty years of age he would "change his course of life, whatever it might then be." Accordingly, he resigned and left Edge Moor, on May 1, 1886. However, hoping he would return, the Company did not fill his place for some time.

He sailed for England early in May, 1886, and spent five months traveling in England, Wales, France, Switzerland, and Germany. Shortly after his return, he was recalled to Edge Moor to design a proposed elevated railroad in Philadelphia, Pa. On the completion of this work, he opened an office in New York, N. Y. He patented the "Pegram truss," which he had designed to simplify and cheapen truss-bridge construction, and first introduced it in 1889 in the construction of a 200-ft pin-connected railway span over the Verdigris River, in Indian Territory, for the Missouri Pacific Railway Company.

Closing his New York Office in 1889, Mr. Pegram became Consulting Engineer with the Missouri Pacific Railroad Company at St. Louis, having charge of new bridges, and also, under Mr. James W. Way, the Chief Engineer, the construction of new lines. The System then comprised about 7 500 miles of track. The new lines, built during Mr. Pegram's period of service were from Coffeyville, Kans., to Fort Smith, Ark.; Kansas City to Fort Scott, Kans.; and Monroe to Alexandria, La. The "Pegram truss" was used for all new bridges and several replacements on old lines. The bridge across the Arkansas River, at Fort Smith, consists of three spans of 200 ft each, and a span 350 ft in length, all Pegram trusses.

In 1891, the Terminal Association of St. Louis, formed of the seven railroads terminating in that city, decided to build a Union Station. Several plans were considered, and that proposed by Mr. Pegram was unanimously approved by a Committee composed of the Chief Engineers of the several railroad companies and by H. P. Taussig, M. Am. Soc. C. E., President of the Terminal Association. The train-house is 610 ft wide and 700 ft long, covering 32 tracks. The roof is carried by five spans of Pegram trusses, the upper chords forming a circular arc.

On February 1, 1893, Mr. Pegram became Chief Engineer of the Union Pacific System, then composed of about forty railroads having about 9 000 miles of track, only about 35 miles of which were double-tracked. He assumed this position under President S. H. H. Clark, with whom he had been associated while Mr. Clark was Vice-President and General Manager of the Missouri Pacific Railway Company. He remained in this position for five years, during which many new steel bridges were built, chiefly in Wyoming, Idaho, and Kansas. In most of these, Pegram trusses were used. The Town of Pegram, Idaho, was named in his honor.

In the fall of 1896, Mr. Pegram was called to New York City for a consultation with the late Jay Gould, who requested him to make an examination of the elevated railroad structures. Mr. Gould had been advised that the Sixth Avenue Line would have to be replaced. Mr. Pegram, on examination, reported in favor of making extensive reinforcements over a long period of time, on the completion of which he held that the structures would serve safely for many years. This report, doubtless, led to his being called to New York in 1898 to become Chief Engineer of the Manhattan Railway Company. In this capacity he was intimately associated with the development of transit facilities in New York City from 1898 until his death.

The development of electric traction prior to 1899 made possible a large increase in the carrying capacity of the existing elevated railroads by the use of this new motive power. It also made possible the use of subways for city transit. Increased transit facilities in the city were urgently needed and the construction of subways followed rapidly upon the development of this new motive power, and elevated extensions followed a little later.

When Mr. Pegram came to New York City in 1898 there were elevated railroads with a total of 167 single-track miles operated by steam locomotives, and these were the only rapid transit railroads operating in the city. They carried about 250 000 000 passengers per yr, with much congestion. In 1937, there were 780 single-track miles of elevated and subway railroads operating in the city, all with electric motive power, and carrying 1 900 000 000 passengers per yr.

During its early period this development was pioneering work, both in construction and equipment, to the success of which Mr. Pegram made a large contribution. Outstanding examples of this are the reinforcement of the existing elevated railways in Manhattan and The Bronx for electric traction; the construction of the 74th Street Power House—the largest and most efficient power-generating station in the world at that time; the construction of seven subsidiary sub-stations; extensions of the elevated lines and completion of third track and its equipment, the latter work being carried on without interruption of train operation; the construction and equipment of the first railroad tunnel under the East River, involving much difficult and novel treatment; the equipment of subway lines, comprising electrical road equipment, signaling, drainage, and ventilation, totaling 157 single-track miles; the construction of twelve subway power sub-stations; the complete construction of parts of the subway lines; the construction of subway platform extensions and a new deep-tunnel station, all without interruption of train operation. This work involved many unavoidable hazards and required much novel treatment and unceasing care.

During much of this work, Mr. Pegram was Chief Engineer of both the Operating Company and the Subway Construction Company, the latter Company as a subsidiary of the Interborough Rapid Transit Company constructing seven sections of the more difficult subway work, in particular, the connecting sections between the operating subways and the new work, where the safety of train operation was involved. In addition, from 1912 to 1924, Mr. Pegram was Chief Engineer of the New York Railways Company, operating a large part of the surface lines in Manhattan. All these activities were conducted in close co-operation with the State and city agencies, in which his ability as an engineer was supplemented by a genius for friendship, and the success of the co-operative effort, necessary for the accomplishment of the vast and complex engineering work of rapid-transit development, owed much to the genial atmosphere of mutual respect and friendliness, with which he was able to surround meetings of many and diverse personalities, with different points of view and different interests, and to bring them into effective co-operation.

George Herndon Pegram was a great Engineer, measured not only by volume, variety, and character of work done under his direction, but still more by the influence he exerted on those who participated with him in this work. He was a man of strong convictions, but this never impaired his sense of fairness nor his consideration of the viewpoints of others. He was modest—even diffident—and " never spoke out of his turn." When he spoke it was clearly and to the point. He treated with the same kindly courtesy all with whom he came in contact, from the highest to the lowest. Being very human, he sometimes lost his temper, but invariably followed this with some consoling or humorous remark that wiped out the sting of his words and restored good feeling. He found time to cultivate qualities as a man which brought to him a large circle of friends outside of, as well as within, the Engineering Profession. He had a keen sense of humor, and the rare faculty of enjoying a good joke on himself as well as on the other fellow. He was always welcome in any company, whether it was gathered together for professional discussion, or for good fellowship, being an appreciative listener as well as an entertaining talker.

His professional staff was ever loyal and devoted, knowing well he lived by the rule that true loyalty works downward as well as upward, extending all the way down the line. No one misses him more than those who have served under him.

He was peculiarly fortunate in retaining to the end of his long and eventful life a youthful interest in people and events. He was a great lover of music, Wagner being his favorite composer and grand opera his favorite entertainment. Another favorite avocation was sailing and deep-sea fishing.

Despite his conscientious absorption in his professional work, he was most devoted to his home and family. Although he was known to many as a great engineer, it was the privilege of comparatively few to appreciate fully his sterling personal character as son, brother, husband, father, and friend. In passing he left voids in many lives, never to be filled, but his good works, his generosity, his kindliness, and his good fellowship have left imprints on these lives that will endure for long down the ages.

Mr. Pegram was President of the Society during the period of the World War and conducted its affairs during that time of stress in such a manner that the Society emerged stronger than ever before. Under his guidance as President, the Society moved its headquarters from West 57th Street to the Engineering Societies Building, part of which it now occupies; and it joined with the other three large National Societies in the creation of Engineering Council and assisted in the formation of what is now United Engineering Trustees, Inc.—agencies providing the machinery for concerted effort in all matters concerning the profession.

When Honorary Membership was conferred upon Mr. Pegram at the Annual Meeting of the Society on January 20, 1932, he was addressed as follows: "The Honorary Membership now conferred upon you completes the list of rewards which this Society can give to members who have held its highest office and have rendered outstanding service to the profession and inferentially it should carry with it a recognition of the possession of human qualities which endear the man to those with whom he comes in contact."

It was characteristic of Mr. Pegram that, in attempting to respond, he broke down in tears.

Mr. Pegram served on a number of the important Committees of the Society. He was also Past-Trustee of Engineering Foundation; member of the American Society of Professional Engineers; member and Past-Director of the Engineers' Club of New York; member of the Virginia Society of New York; and Doctor of Laws of Washington University.

An examination of the *Transactions* shows that he presented his first paper to the Society in 1884, four years after his admission, and that this paper was followed by fifteen other papers and discussions, most of them relating to bridge and railroad subjects.

The death of George Herndon Pegram on December 23, 1937, brought to a close the long career of one of the most distinguished engineers in the United States. He was one whom engineers and others delighted to honor for his exceptional character and ability and his charming personality.

Mr. Pegram was married, at St. Louis, on September 8, 1897, to Jessie Merrilees Crawford, who survives him. He is also survived by his two daughters, Jean Forsyth Pegram and Mrs. Horace M. Buck; also by his brother, Frank R. Pegram and his sister, Mrs. Minnie (Pegram) Fabian.

Mr. Pegram was elected a Junior of the American Society of Civil Engineers on April 7, 1880; a Member on January 3, 1883; and an Honorary Member on October 5, 1931. He served as a Director of the Society from 1902 to 1904; as Vice-President in 1909 and 1910; and as President in 1917.

AMBROSE SWASEY, Hon. M. Am. Soc. C. E.[1]

DIED JUNE 15, 1937

Ambrose Swasey was born on December 19, 1846, near Exeter, N. H., the youngest child of Nathaniel and Abigail Swasey. At an early age his formal education (received in the elementary schools of Exeter) ceased, and he began his mechanical training as an Apprentice in the Exeter Machine Works, apparently following a natural bent in occupation. This, later, through his many awakened talents, developed into a wonderfully long and successful career.

From 1865 to 1869 Mr. Swasey remained with the Exeter Machine Works, leaving this Company to go, as a Master Machinist, to the well-known shops of Pratt and Whitney, at Hartford, Conn. While at Exeter he began his life-long association with Mr. Worcester R. Warner, who accompanied him to the works of Pratt and Whitney, also as a Master Machinist. In 1880, Mr. Swasey and Mr. Warner joined forces and fortunes through the formation of their own business in Chicago, Ill., under the name of Warner and Swasey, thus founding an organization destined to live many years and to develop a reputation widely and favorably known in the United States and in foreign countries. In 1881, the business was moved to Cleveland, Ohio, where the partners made their permanent homes and where the business is still conducted by their successors.

Mr. Swasey, early in his career, developed improved processes of manufacturing machine gears, and the first method of generating and cutting teeth of spur-gears entirely by mechanical processes. His engineering and technical accomplishments continued largely in connection with designing and building machines and instruments of precision both for commercial and scientific purposes. He either perfected, or made possible, through his expert and inspiring aid and direction in the work of the Warner and Swasey Company, the design and manufacture of high quality turret lathes, high-class astronomical instruments, and especially the construction and mounting of many notable telescopes. Such great telescopes include that at the Lick Observatory with its 36-in. lens, the Naval Observatory telescope, and the 40-in. Yerkes refracting telescope which remains the largest in the world. Several great reflecting telescopes also added to Mr. Swasey's fame; the 72-in. instrument of the Dominion Astrophysical Observatory, in British Columbia, the 69-in. telescope at Ohio Wesleyan University, and the most recent, the 82-in. reflector for the University of Texas. Of great importance was also the dividing engine, used in graduating with extreme accuracy the great circles necessary in astronomical observation of the stars, reported to be unexcelled in accuracy by any other dividing engine.

---

[1] Memoir prepared by Robert Hoffmann, Hon. M. Am. Soc. C. E., and Ralph Budd, M. Am. Soc. C. E., largely from the article by W. W. Campbell, reprinted from the publications of the Astronomical Society of the Pacific, August, 1937; from the citation presented at the time Mr. Swasey was made an Honorary Member of the American Society of Civil Engineers, and at the time of presentation of the John Fritz Medal; also from the August, 1937, issue of *Mechanical Engineering*. Additional information may be obtained from these sources.

Although Mr. Swasey's name will always be remembered through his accomplishments in the field of science and the manufacturing successes of Warner and Swasey, he also showed willingness to devote much of his time, energy, and means to aid educational institutions, assisting civic organizations, and above all to promote science and the welfare of engineers and engineering. Among Mr. Swasey's many benefactions may be listed those to the following educational institutions: The Science Building for the University of Nanking, the Christian Association Building of Canton Christian College (now Lingman University, China), the Denison University Chapel and Observatory, the Colgate-Rochester Divinity School Library Building, the endowment of a Chair of Physics at Case School of Applied Science, and an observatory to the same institution, presented jointly by Mr. Swasey and Mr. Warner.

Especially appreciated by the entire Engineering Profession was Mr. Swasey's active interest in the welfare of engineers and in the promotion of work undertaken by them. His interest in securing the building occupied as the home of the four great engineering societies in New York, N. Y., and built through the generosity of Andrew Carnegie, will long be remembered. Since 1914, Mr. Swasey gave generously of his means and much of his time and support to establishing the Engineering Foundation, having for its objective "the furtherance of research work in engineering, or for the advancement in any other manner of the profession of engineering and the good of mankind."

It is eminently fitting that Mr. Swasey's unselfish devotion to the welfare of others should have been recognized and honored by many. In addition to honors from the educational institutions heretofore mentioned, there were also conferred the following: From the Government of France, Chevalier of the Legion of Honor in 1901, and Officer of the Legion of Honor in 1921; the Cleveland Chamber of Commerce Medal for Distinguished Public Service; the Gold Medal of the Franklin Institute; the Gold Medal of the American Society of Mechanical Engineers; Washington Award by the four National Engineering Societies, and the Western Society of Engineers made in 1934; in 1936, the Gold Medal established by President Hoover to be awarded in recognition of distinguished services rendered in the engineering field; and the John Fritz Gold Medal awarded by the Engineering Profession of America in 1924.

Mr. Swasey was a Charter Member, Past-President, and Honorary Member of the American Society of Mechanical Engineers; Past-President and Honorary Member of the Cleveland Engineering Society; Honorary Member of the American Institute of Electrical Engineers; Member of the American Astronomical Society; the Institute of Mechanical Engineers; the British Astronomical Society; Fellow of the Royal Astronomical Society; Member of the American Philosophical Society, and the National Academy of Sciences; and also a Trustee of Western Reserve University, Denison University, the University of Nanking, and of the Case School of Applied Science.

Although his early schooling may appear meager and limited, Mr. Swasey's life is another example showing how learning and culture may be developed through the school of experience and by individual effort, even if early book learning, as judged to-day, seems to have been largely lacking. Ambrose Swasey was a highly educated man measured by any standard—a fact well attested by the respect and recognition given his career and accomplishments by educational institutions. The degree of Doctor of Engineering was conferred upon him in 1905 by the Case School of Applied Science, at Cleveland, Ohio; the degree of Doctor of Science in 1910 by Denison University, at Granville, Ohio, in 1924, by the University of Pennsylvania, at Philadelphia, Pa., and in 1931, by Brown University, at Providence, R. I. The degree of Doctor of Laws was also conferred upon him by the University of California, in Berkeley, Calif., in 1924, by the University of Rochester, at Rochester, N. Y., in 1925, and by the University of New Hampshire, at Durham, N. H., in 1930.

The career of Ambrose Swasey was a long and eventful one, so many sided that his accomplishments, distinguishing him as a great man personally, cast reflected credit and honor on the many interests and organizations with which he was affiliated rather than to any single cause or interest. He belonged to many—to mankind. Rarely is the opportunity afforded and the necessary ability, willingness, and training given to one individual to do the things that fell to the lot of Mr. Swasey. Long life, success in business, a keen mind, an engaging personality, and impressive appearance, all contributed to make him and his career an example that engineers may well look upon as an ideal well worthy of aspiration.

Mr. Swasey was married in 1871 to Lavinia D. Marston, whose death preceded his by twenty-four years. There were no children.

Ambrose Swasey was elected an Honorary Member of the American Society of Civil Engineers on June 6, 1921.

ROBERT ADAM, M. Am. Soc. C. E.[1]

DIED APRIL 15, 1937

Robert Adam was born on February 21, 1866, at Paisley, Scotland, the son of Robert Adam—a member of a Border family. He was educated at Heriot-Watt College, in Edinburgh, Scotland, and from 1882 to 1885, served his Apprenticeship under Mr. A. S. Biggart. He received his training under Mr. R. E. Middleton, acting as Assistant to Mr. J. Phillips.

The following year, at the age of twenty, Mr. Adam engaged in his first engineering work which was in connection with the construction of the Firth of Forth Bridge in Scotland. He continued in this work for four years.

---

[1] Memoir prepared from data supplied by the family and on file at the Headquarters of the Society.

In 1890, he joined the staff of Messrs. James Young and Company, Contractors, and worked on the Blane Valley Section of the Glasgow Water-Works (five miles of aqueduct in tunnel); and from 1891 to 1893 he was Engineer to the same firm on the Stobcross Section of the Glasgow Central Railway, and the Stobcross Section of the Lanarkshire and Dumbartonshire Railway. The work was principally tunneling and cut and cover.

As Assistant to the late Sir Ernest William Moir, M. Am. Soc. C. E., Mr. Adam served for two years as Engineer-in-Charge of Approaches on the Blackwall Tunnel.

In 1895 he joined the staff of Messrs. S. Pearson and Son Limited, Contractors, as Engineer during the construction of the Surrey Commercial Dock, in London, England. A year later he was transferred to the staff of the same firm in Mexico and served as Chief Assistant Engineer on the Vera Cruz Harbor Works, Drainage, and Water Supply of the City of Vera Cruz, under J. B. Body, M. Am. Soc. C. E., as Chief Engineer. He continued in this work until 1900, when he was appointed Engineer of the Salina Cruz Harbor Works, as well as of drainage and water supply.

From 1902 to 1905 Mr. Adam was Consulting Engineer to Messrs. S. Pearson and Son for the drainage and water supply of the Vera Cruz Harbor Works, the Coatzacoalcos Harbor Works, and the Salina Cruz Harbor Works, at a cost of about $50 000 000.

He opened his own office as Consulting Engineer in the City of Mexico, Mexico, in 1906, remaining there until 1912, when he returned to England and continued his practice. Because of his vast engineering knowledge, he was held in high esteem as a Consultant.

Mr. Adam was created an Officer of the British Empire for his special service during the World War. He was engaged by the War Office on the Railway Material Branch, and practically built up that section of war work, retiring from it only at the end of the war. He was a Member of the Institution of Civil Engineers, in London, England.

He is survived by his widow, Lena (Phillips) Adam, and by two daughters, Dr. L. C. Adam and Dr. F. A. Adam-Thomson.

Mr. Adam was elected a Member of the American Society of Civil Engineers on May 2, 1900.

WILLIAM AUGUSTIN AIKEN, M. Am. Soc. C. E.[1]

DIED OCTOBER 5, 1935

William Augustin Aiken was born August 29, 1851, at Baltimore, Md. Both his parents came of old Colonial stock. His paternal great-great-grandfather came from the south of Scotland toward the close of the Seventeenth Century, one of two brothers, of whom one settled in New England and the other in New York. A first cousin settled in South Carolina, whence the Aikens of that State.

---

[1] Memoir prepared by W. D. Aiken, Assoc. M. Am. Soc. C. E.

His grandfather, John Aiken, was born in Poughkeepsie, N. Y., and was graduated from Yale University, at New Haven, Conn., in 1798. Later, he was admitted to the bar and practised law in Troy, N. Y. Through his paternal grandmother, who was a Cooke, he was connected with the Braesteds and Motts of New York.

His father, Dr. William E. A. Aiken, a distinguished Chemist and Toxicologist, was Professor of Chemistry in the Medical School of the University of Maryland, at Baltimore. He lectured there for fifty years, and was Professor Emeritus at the time of his death. His mother was Rebecca Josephine Nicholson whose ancestors came to the United States from Berwick-on-Tweed, England, at the beginning of the Eighteenth Century, settling first in Virginia, and, later, moving to Easton on the eastern shore of Maryland, where she was born.

The Nicholsons from the earliest to the present time have been Navy people. Mr. Aiken's grandfather, Commodore Joseph Nicholson, was in command of the American Naval defense of Baltimore in the War of 1812. His great-aunt was the second wife of Albert Gallatin, Secretary of the Treasury in Jefferson's Administration, and is buried in Trinity Churchyard, in New York City. Through his mother's family, William Augustin Aiken was closely connected with the Wilmer, Lardner, Lippincott, Biddle, and Rush families of Philadelphia, Pa.

Mr. Aiken attended the Jesuit College, Loyola, in Baltimore, and was graduated in 1869 with the degree of Bachelor of Arts. He then entered Rensselaer Polytechnic Institute, at Troy, as a Sophomore in the Class of 1872, and was graduated with the degree of Civil Engineer. It is of interest that his father was a special student in the first class to be graduated from the Institute.

After a year's preliminary experience with the Western Maryland and Pennsylvania Railroad Companies, Mr. Aiken went to California in 1873, and for six years had a varied experience, embracing field work on irrigation canals in the San Joaquin Valley, water supply investigations for the City of San Francisco, original surveys for the Golden Gate Park in that city, preliminary location and construction work on railroads throughout California, and, for three years, he was engaged in mining and metallurgical work in Nevada in association with the late William Starke Rosecrans, M. Am. Soc. C. E.

Returning East in 1879, Mr. Aiken associated himself with Colonel John G. Clark, who had been prominent as an Engineer in the Armies of the South during the Civil War. At this time the railroads running south from Washington, D. C., were being rehabilitated and Mr. Aiken had charge of the replacement of numerous bridges and was engaged in this work for several years.

Growing out of this experience he joined the Morse Bridge Company, of Youngstown, Ohio, in charge of its Chicago, Ill., Office, and for several years was engaged in contracting in the Northwest.

Upon the dissolution of the Morse Bridge Company, Mr. Aiken became associated with the Pittsburg Testing Laboratory and located at Athens, Pa.

As its Resident Engineer at the shops of the Union Bridge Company he had charge of the fabrication of the Poughkeepsie Bridge, as well as other important work, notably the manufacture of the eye-bars for the Hawksbury River Bridge, in Australia, which were forged from Scotch steel, shipped in bond, and later reshipped to Australia.

After some years of inspection work at Athens, Mr. Aiken accepted a position as General Manager and Chief Engineer of the Mt. Vernon Bridge Company, at Mr. Vernon, Ohio. He largely re-organized this highway bridge shop, installing facilities for heavier construction and, over a period of several years, built many bridges in the Middle West.

Resigning from this connection Mr. Aiken returned to his association with the Pittsburg Testing Laboratory as its Chicago Representative, and was active in its interests during the 1893 World's Fair in that city.

When the Pittsburg Testing Laboratory discontinued its Chicago Office, Mr. Aiken entered private practice and was engaged upon important construction, such as the United States Government bridge over the Mississippi River, at Rock Island, Ill., under Ralph Modjeski, M. Am. Soc. C. E., and the Duluth and Superior Bridge under the late Alfred Pancoast Boller, M. Am. Soc. C. E.

When the contract for the original subway in New York was finally signed early in 1900, the attention of the Chief Engineer, the late William Barclay Parsons, Hon. M. Am. Soc. C. E., was called, without Mr. Aiken's knowledge, to his experience with structural materials, with the result that he was subsequently appointed Division Engineer with the title of General Inspector of Material. Mr. Aiken organized the Department of Inspection of Material and for eight years it functioned efficiently and to the satisfaction of the Chief Engineer.

Resigning after eight years' service on the subway work, Mr. Aiken associated himself with the H. S. Spackman Engineering Company, of Philadelphia, and, as Vice-President, had charge of the Chemical and Physical Laboratories. It was a source of pride to Mr. Aiken that for several years a large amount of his work came directly through his former connection on the subway, from General Parsons and his associates.

When the United States entered the World War, Mr. Aiken had retired from the Spackman Engineering Company, and was prevented from obtaining a commission in the Engineer Corps by a serious injury to his hip due to a fall. He was obliged to content himself by doing "his bit" as a Testing Engineer in the United States Ordnance Department. He was located at several plants and, finally, at Pottstown, Pa., which plant was said to have been the only one, except Government Arsenals, from which no finished shells were rejected.

After the war he returned to his favorite work of material inspection and was engaged on several large projects through his association with General Parsons, such as dry dock construction, at Portsmouth, Va., Navy Yard; concrete warehouse construction, in Havana, Cuba; and a concrete dam across the Hudson River, at Glens Falls, N. Y., where for three years he had charge of the manufacture of concrete. Mr. Aiken considered his association with General Parsons on the original Rapid Transit work, and subsequently, as the happiest professional engagements of his career.

Owing to increasing physical debility due to an earlier injury Mr. Aiken was not active in business after about 1930.

He was a devout member of the Roman Catholic Church and his life conformed strictly to the requirements of his faith.

Mr. Aiken held membership for many years in the American Society for Testing Materials and was active in that Society, serving as Chairman of several committees and presenting numerous papers at its Annual Conventions.

In 1881, he was married to Jennie M. Drees, of Xenia, Ohio, whom he met in Columbia, S. C. He is survived by his widow, a son, W. D. Aiken, Assoc. M. Am. Soc. C. E.; a daughter, Mrs. Jean A. Reinke, and two grandchildren.

Mr. Aiken was elected a Member of the American Society of Civil Engineers on October 2, 1889.

WILLIAM BULLARD ALLEN, M. Am. Soc. C. E.[1]

DIED JANUARY 9, 1938

William Bullard Allen was born in Indianapolis, Ind., on March 12, 1863. He was the son of William Allen and Martha (Carter) Allen. He received his early education in the public schools in Indianapolis, and, later, attended Hanover College, at Hanover, Ind.

Mr. Allen began his engineering career in 1881, on surveys for, and the construction of, the Cincinnati and Georgia Railroad (later, a part of the Southern Railway); and for the following four years he was active on surveys and construction on the East Tennessee, Virginia, and Georgia Railroad, the Northern Alabama Railroad, and also on the railroad belonging to the Cahaba Coal Mining Company, between Woodstock and Blocton, Ala.

He then became, for a time, an Assistant Engineer with the Guatemala Northern Railroad Company, in Guatemala. On his return to the United States he was engaged in like capacity for the Kansas City, Memphis and Birmingham Railroad Company. Afterward, he was an Assistant Engineer in the Maintenance-of-Way Department of the Louisville and Nashville Railroad Company, between Decatur and Montgomery, Ala.

In 1888, Mr. Allen conducted a survey for the Mexican Government for a railroad from Jiménez to Balleza, Mexico, upon the completion of which, he entered the service of the Texas and Pacific Railway Company as an Assistant Engineer. From this position he was, successively, promoted to that of Division Engineer, Assistant Resident Engineer, and Resident Engineer, in which latter capacity he had charge of bridges, buildings, and water service for the entire System, which was then about 1 500 miles.

---

[1] Memoir prepared by J. F. Coleman, Past-President and Hon. M. Am. Soc. C. E.

In May, 1892, Mr. Allen resigned the latter position to take charge of an extension of the Natchitoches Railroad, in Louisiana; and in May, 1893, he entered the service of the Tennessee Coal, Iron, and Railroad Company, in which service he remained until his retirement on October 1, 1932.

During this time, Mr. Allen was also Manager of the Land Department, in charge of all the Company's real estate until March, 1918. Subsequently, he was Manager of the Chickasaw Utilities Company and of the Chickasaw Land Company (subsidiaries of the Tennessee Coal, Iron, and Railroad Company). Later, he was made Agent in the Executive Department of the Tennessee Coal, Iron, and Railroad Company, Assistant to the President of the Ensley Land Company, Vice-President of the Birmingham Southern Railroad Company, and Chairman of the Executive Committee, Port of Birmingham Company.

He was married on November 3, 1902, to Lucy Beall, of Birmingham, Ala., who survives him. He is also survived by a sister, Mrs. Edward M. Hughes, and a niece, Mrs. N. E. Nichols.

In the course of his lifetime, Mr. Allen was never robust, and suffered almost constantly from ill health. His rather remarkable advancement in his profession was the result of an indomitable will, and a stubborn courage that refused to recognize or admit his bodily weakness.

He was a very reserved man, and slow to give his friendship. Notwithstanding which he had a host of friends, and wielded an influence upon the lives of others far beyond his own realization.

In his passing the Engineering Profession has lost a noble soul, a man of high ideals, and of unswerving integrity.

Mr. Allen was elected a Member of the American Society of Civil Engineers on February 3, 1904.

WILLIAM DELANO ARMSTRONG, M. Am. Soc. C. E.[1]

DIED NOVEMBER 5, 1937

William Delano Armstrong was born at Wailuku, Maui Island, Hawaii, on June 20, 1872. His father, Goodale Armstrong, was a member of one of the early pioneer families of California. He was a merchant in Marysville, Calif., after his migration overland from Cleveland, Ohio, in which city, Goodale Park still exists as a gift of the Goodale family. His mother, Lucia

---

[1] Memoir prepared by Earle A. Burt, M. Am. Soc. C. E.

Peck, was the daughter of a missionary family from New England, who came to California *via* Cape Horn during the early period.

The early years of William Armstrong's life were spent in the Hawaiian Islands, where he received his elementary and preparatory education. For a period of two years he attended Oahu College, in Honolulu, as a student in Civil Engineering, after which he worked in an iron foundry in the same city for a period before entering the service of the Olinda Oil Company as its Honolulu Representative in California.

During 1901 and 1902, Mr. Armstrong was employed as Chief Draftsman in the office of the Los Angeles Railway Company, subsequently joining the Staff of the Pacific Electric Railway Company, as a Draftsman, with which he held the position of Chief Draftsman for the years from 1904 to 1907. At the end of this engagement, he became associated with the United States Reclamation Service and spent the years from 1907 to 1909 on work at the Granite Reef Project, in Arizona.

The formation of the Los Angeles County Highway Commission in 1907 and the subsequent Good Roads Bond Issue in 1908 created one of the pioneer highway organizations of the West, and in 1909, Mr. Armstrong joined the forces of the Highway Commission as Structural Designer, thus entering a field of endeavor which was to become his principal life work. In 1914, the work of the Highway Commission was delegated to the newly organized Los Angeles County Road Department, with which his services were continued in the positions of Senior Structural Draftsman, Bridge Draftsman, and Senior Bridge Draftsman, respectively, until 1925, at which time he was appointed Bridge Engineer, with the responsibility of directing the design and construction of all bridge and structural work of the Road Department. In this position he continued his work until the time of his death.

Mr. Armstrong's personality was of the type which has become known, in the popular mind, as typical of the engineer, in that his work was one of his paramount interests. On the other hand, to those who knew him well, his quiet, witty, gentlemanly disposition made his presence in any gathering a source of pleasure and enjoyment. The people of Los Angeles County who really knew his work will be, for many years, reminded of him as, from time to time, they pass over the innumerable structures into which his life and ambition have been incorporated. The public service, to which the best years of his life were dedicated, is benefited, and the esteem which public employees should warrant, is improved by the type of man which he exemplified.

In 1902, Mr. Armstrong was married, at Los Angeles, to Lillian Bovard, the daughter of Dr. Marion McKinley Bovard, and Jean (Allen) Bovard, pioneer of co-education at DePauw University, at Greencastle, Ind. He is survived by his widow and two brothers, Frank and Wade Armstrong.

He was a member of the Sons of the Revolution, and of Pentalpha Lodge, F. and A. M., of Los Angeles.

Mr. Armstrong was elected a Member of the American Society of Civil Engineers on June 10, 1929.

RICHARD I. DOWNING ASHBRIDGE, M. Am. Soc. C. E.[1]

DIED JULY 26, 1936

Richard I. Downing Ashbridge was born on September 22, 1861, at Ondawa Farm, near Downingtown, Pa. He was the son of Abram S. Ashbridge and Elizabeth (Downing) Ashbridge, both descendants of Colonial families. He was of the sixth generation from George G. Ashbridge, who represented the County of Chester in the Colonial Assembly for a period of thirty years, from 1743 to 1773. The County of Chester then comprised all of the State of Pennsylvania west of Philadelphia County and south of the Schuylkill River.

Mr. Ashbridge prepared for college at the Chester Valley Academy, in Downingtown. Later, he attended the University of Pennsylvania, at Philadelphia, Pa., from which he was graduated, in 1881, with the degree of Bachelor of Science in Civil Engineering. During one or more of his summer vacations, he was employed by the United States Geological Survey.

From June, 1881, to October of that year, Mr. Ashbridge was Topographer for the Central Virginia Mining Company. He then went West, and from November, 1881, through November, 1882, he was Assistant Engineer during the construction of the Little Falls and Dakota Branch of the Northern Pacific Railway. The next year (December, 1882, to December, 1883), he was Assistant Engineer in charge of two 12-mile Divisions of the Duluth and Iron Range Railroad, in Northern Minnesota. While engaged in this work, he lived under canvas a considerable part of the time, with the thermometer going as low as — 40° F.

Returning East, in April, 1884, Mr. Ashbridge took a position with the Department of Public Works in the Bureau of Surveys of the City of Philadelphia, and from then until April, 1888, he served in various capacities as Rodman, Leveler, and Assistant Engineer in charge of construction and location of a new intercepting sewerage system. For the next year, until June, 1889, he was Engineer in charge of the construction of the City Line Bridge, over the Schuylkill River.

From June, 1889, to January, 1890, he was employed as Assistant Engineer in charge of a section of the Ohio Extension of the Norfolk and Western Railroad. Mr. Ashbridge then became Engineer of the Roanoke Development Company, and, until August, 1890, was in charge of the laying out and erection of four bridges over the Roanoke River, and of grading and draining the town site and the construction of buildings.

In August, 1890, he returned to Philadelphia, and until September, 1894, was once more with the Bureau of Surveys of the Department of Public Works, this time as Engineer in charge of the location and construction of the Wissahickon Intercepting Sewer and its branches. From September, 1894, to November, 1895, he was in charge of the construction of the drainage system of the Pennsylvania Avenue (Philadelphia) Subway and Tunnel, embracing about seven miles of sewers built into the tunnel.

---

[1] Memoir prepared by Whitney Ashbridge, Assoc. M. Am. Soc. C. E.

As Engineer in charge of the Hydrographic Corps, of the City of Philadelphia, he supervised the surveys for, and the excavation of, the ship channel in the Schuylkill River.

He was Assistant Engineer on lines and grades for the Pennsylvania Avenue Subway and Tunnel from August, 1896, to September, 1900. From that time until March, 1902, he served as Assistant Engineer on the improvement, extension, and filtration of the Philadelphia Water Supply. During this engagement Mr. Ashbridge assisted in the construction of the Belmont Water-Works, and the Torresdale Filter Plant, both of which are still in operation.

Becoming First Assistant Engineer of the Bureau of Filtration, City of Philadelphia, in March, 1902, he held that position for a year, leaving in 1903 to become Engineer for Stern and Silverman, of Philadelphia, in charge of the construction of various railway lines, including the following: In 1904, the New Jersey Short Line Railroad (later, a part of the Public Service Corporation of New Jersey); in 1906, the Atlantic City and Shore Railroad; in 1907, the Atlantic City and Ocean City Railroad; in 1911, the Chester and Philadelphia Railroad; and, in 1917, the Salem and Pennsgrove Traction Company.

For more than twenty-five years prior to his death, Mr. Ashbridge held the position of Chief Engineer of the Atlantic City and Shore Railroad Company.

He was the author of a widely used practical engineering book entitled "Civil Engineering Specifications and Contracts," which he published in 1914. He also wrote chapters on subjects with which he was familiar for various engineering textbooks.

At the time of his death, and for many years prior thereto, Mr. Ashbridge was a Vestryman of St. James Protestant Episcopal Church, in Downingtown.

A lover of music, painting, and flowers, his main interest, outside his profession, was floriculture. Most of his spare time during the spring and summer months was spent in the garden of his home at "Ondawa," just east of Downingtown. Although his particular hobby was the raising of flowers, he was interested in all kinds of horticulture. For many years, he was a member of the Engineers' Club of Philadelphia.

He is survived by four sisters, Mrs. J. D. Perkins, Mrs. C. S. Rutter, Mrs. Henry Ecroyd, and Eleanor Ashbridge; and by two brothers, A. S. Ashbridge, Jr., and Joseph S. Ashbridge.

Mr. Ashbridge was elected an Associate Member of the American Society of Civil Engineers on September 3, 1902, and a Member on April 30, 1907.

JOHN LELAND BECTON, M. Am. Soc. C. E.[1]

DIED JANUARY 8, 1938

John Leland Becton, son of George and Mollie Becton, was born at Goldsboro, N. C., on October 24, 1885. His technical education was obtained at the

---

[1] Memoir prepared by a Committee of the North Carolina Section, consisting of W. C. Riddick, J. D. Spinks, and J. E. Willoughby, Members, Am. Soc. C. E.

North Carolina State College of Agriculture and Engineering, at Raleigh, N. C., from which he received the degrees of Bachelor of Engineering in 1908, and Civil Engineer in 1913.

Mr. Becton began his professional work in Wilmington, N. C., in a subordinate capacity in 1908; and, in 1911, he established there a general engineering practice. During the development and progress of that practice his work covered farm and drainage surveys; reclamation projects, such as prevail in the flat plains of Eastern North Carolina; industrial railways and industrial plants; the design and construction of bridges, docks, and terminals; water and sewerage systems; and other municipal projects.

Positions held by him in public service include: Deputy City Engineer, of Wilmington; Assistant Chief Engineer, of the Liberty Ship Building Corporation (a World War agency for building concrete ships); Member of the Board of Trustees for Greater University of North Carolina; President of the North Carolina State College Alumni Association; Member of Board of Engineering Registration for North Carolina; President of the Wilmington Chamber of Commerce; and Chairman of the Board of Stewards of Grace Methodist Episcopal Church South. A short time before his death, he was elected Lay Delegate to the 1938 General Conference of his Church.

Mr. Becton took an active part in the work of the North Carolina Society of Engineers, and the North Carolina Section of the Society, in both of which he held many official positions, including that of President. He held membership in Phi Kappa Phi (Honor Society), the Rotary Club, Cape Fear Club, Cape Fear Country Club, and the Carolina Yacht Club, all of Wilmington.

In the practice of his profession, Mr. Becton undertook only such work as could be done by himself, or by his assistants under his personal direction, thus insuring that the client would receive clear, seasoned, engineering judgment. He never sought clients; he was never without them. The monetary return from his practice was generous, and yet the return in the esteem of those who knew him and his worth was of greater moment to him than the professional fees received, and he will be remembered as a public-spirited, Christian citizen, and as a friend, long after the "gnawing tooth of time" has destroyed all records of his work as an engineer. He was never married.

Mr. Becton was elected an Associate Member of the American Society of Civil Engineers on December 2, 1914, and a Member on June 6, 1921.

CHARLES ROBERT BETTES, M. Am. Soc. C. E.[1]

DIED OCTOBER 29, 1937

Charles Robert Bettes, the son of Edwin Wareham and Eliza (Kinnear) Bettes, was born in Youngsville, Pa., on April 9, 1863. He received his early education in Titusville, Pa., later attending the Columbia Preparatory School and the School of Mines of Columbia University, in New York, N. Y.

---

[1] Memoir prepared by Joseph Goodman, M. Am. Soc. C. E.

Mr. Bettes began his engineering career in 1881 in the New York Office of the construction firm of Charles B. Brush, Inc., where he was employed, until the end of 1893, as Assistant in Charge of Surveys and Construction, chief among which were the water supply structures, including dams, pump-houses, and stand-pipe at Union Corners, N. Y., for the New Rochelle (N. Y.) Water Company; Weehawken Reservoir No. 2, of 30 000 000 gal capacity; and the enlargement of the Queens County Water Company's plant at Far Rockaway, N. Y.

In January, 1894, he accepted the position of Resident Engineer with the Queens County Water Company, designing and constructing its high-service and auxiliary pumping stations, slow-sand iron removal filters, and extensions of its distribution system. In 1897, he was appointed Chief Engineer and, shortly thereafter, General Manager of this Company (which in 1925 became the Long Island Water Corporation), and continued in that capacity until his retirement on June 1, 1931. During most of this time he was also a member of the firm of Tribus and Massa, in New York City, specializing in water supply, sewerage, and sewage disposal, continuing his association with this firm until its dissolution upon the death of Louis Lincoln Tribus, M. Am. Soc. C. E., in 1930.

The Water Company served not only the Rockaways, constituting the Fifth Ward of Queens in New York City, but also about fifteen or more villages in the southwestern part of Nassau County adjoining the Queens County line, and its success was due in a large measure to the combination of technical ability, foresight, and scrupulous integrity possessed by its Chief Engineer and General Manager.

The co-operation of Mr. Bettes with the New York City representative in 1915 was in great part instrumental in the subsequent agreement reached—as regards the Water Company's plant lying within the city's limits—on the rates to be charged to consumers and the compensation to be made the Company for the fire protection furnished. It was one of the early and one of the few instances in the eastern section of the United States where compensation was based upon a fair return of the estimated capital invested in the service, together with a proper allowance for depreciation, taxes, maintenance, and operation, and was cited as a precedent in many subsequent proceedings of a like nature. The aforementioned agreement remained in force until 1931 when the City acquired that part of the Company's plant lying within the city limits.

During his long association with the Water Company, Mr. Bettes saw the areas that he served, which contained many extensive estates, subdivided and developed into the populous urban and suburban communities of the better type with which they have been replaced, and in these developments he took an active part. Despite the demands made upon him by the need of extending and improving the water service to meet the rapid growth of these communities, he found time to be a member of the Chamber of Commerce for the Borough of Queens, a Trustee of the Rockaway Savings Bank, a member of the Executive Committee of the Queens Branch of the Bank of Manhattan, and a Director of the Gibson Building Corporation, of Valley Stream, N. Y. He also took an active interest in the work of the American Water Works Association, having served as Trustee from 1924 to 1926, and as a member of its Executive Committee in 1929; he was also a member of the New England Water Works Association.

Mr. Bettes did not neglect the social and spiritual sides of life. He numbered among his friends many of the leading citizens of Nassau County; and few civic or philanthropic movements of merit were carried through without the benefit of his good judgment and advice. He was a Trustee of the Sage Memorial Presbyterian Church, of Far Rockaway, a Son of the American Revolution, and a member of many Masonic organizations. He was interested in the Boy Scout Movement from its inception; and, in 1937, for his service to the boyhood of America, the National Council, Boy Scouts of America, at Washington, D. C., bestowed upon him the Badge of the Silver Beaver, as a token of his work. Those qualities of tact and patience, courtesy, geniality, and kindliness, which are so greatly stressed in "scouting," were personal attributes which all who came in contact with Mr. Bettes will remember.

Surviving is his widow, the former Frances H. Murray, of Cooperstown, N. Y., to whom he was married in 1902.

Mr. Bettes was elected a Junior of the American Society of Civil Engineers on October 1, 1890; an Associate Member on June 7, 1893; and a Member on June 1, 1909.

JAMES BONNYMAN, M. Am. Soc. C. E.[1]

DIED APRIL 9, 1937

James Bonnyman was born in Lexington, Ky., on July 9, 1879. His parents, George and Sarah Ann (Toner) Bonnyman, had moved to Kentucky from Edinburgh, Scotland, a few years before his birth. He attended preparatory school and the University of Kentucky, at Lexington.

His first work was as a Chainman in Government engineering work near Chattanooga, Tenn. Soon thereafter he became connected, in a subordinate position under the Mining Engineer, with the Durham Coal and Coke Company, the only coal-mining property in Georgia, operating in Lookout Mountain near Chattanooga.

Two years later, Mr. Bonnyman became Assistant Engineer and Roadmaster for the Chattanooga, Rome and Southern Railroad Company (later, a part of the Central of Georgia Railroad Company.

In 1902, for the second time, he became connected with the Engineering Department of a coal mine, being employed as an Engineer and the first

---

[1] Memoir prepared by Alexander Bonnyman, M. Am. Soc. C. E.

Superintendent of the Stearns Coal Company, then under initial development and to-day one of the largest and most important coal companies in Kentucky.

The offer of a position as Division Engineer in railroad work caused Mr. Bonnyman again to leave coal mining, and, from 1904 until 1906, he was Division Engineer in Georgia for railroad companies, principally on the Central of Georgia Railroad, Chattanooga Division, of which he had previously been Assistant Engineer and Roadmaster.

In 1906, at the age of twenty-seven years, James Bonnyman was employed to represent capitalists in New York, N. Y., and Boston, Mass., under the Presidency of Mr. H. M. Atkinson, of Atlanta, Ga., in supervising and consummating the delivery of a $6 000 000 purchase, in the Birmingham, Ala., District, of coal and iron property from the Tutwiller and Adler interests, including several going coal and iron mines and iron furnaces, with a twelve months' time limit to conclude the transaction.

This work was done by Mr. Bonnyman with the title of Treasurer of the Birmingham Coal and Iron Company. It was finished, and full delivery was made in the twelve months' contract period. He was then continued as Treasurer and Acting Manager of the Birmingham Coal and Iron Company.

He was soon made Vice-President and General Manager and continued as Treasurer until the panic of 1907 caught this new Company with several million dollars of unfinished development. As no money was available for continuing the development, and the promoters of this big enterprise could not continue its financing, the Company was forced into receivership, Mr. Bonnyman being first made Receiver and then Trustee in bankruptcy, representing the bondholders and the New York and Boston capitalists, a bank president in Birmingham being Co-Receiver representing local creditors.

In a comparatively short time Mr. Bonnyman and his associates were able to pay all the obligations in full and he, again, became Vice-President and Treasurer, the President under the re-organization being the head of a New York Trust Company.

He continued as the operating head of the Birmingham Coal and Iron Company until about 1912, when, under direction of his President and Directors, he concluded negotiations by which the Company was purchased on a very favorable basis by one of the larger coal and iron corporations, bringing its owners about $12 000 000.

After this achievement, Mr. Bonnyman, in 1912, at the age of thirty-three years, began promoting his own coal and iron mining companies. His first development was the Clinton Mining Company, operating in a 16-ft vein of red hematite ore in Red Mountain, above the City of Birmingham. Later, he organized the Brookside-Pratt Mining Company which developed several coal mines in the Birmingham District, being one of the most important commercial coal-mining companies in the district.

In 1916, Mr. Bonnyman sold the Clinton Mining Company of which he was the promoter and President to the Gulf States Steel Corporation. In 1922 he resigned as President and sold his interest in the Brookside-Pratt Mining Company, moving to Cincinnati, Ohio, to join interests with his older brother, the writer, in the operation and development of several coal companies in Virginia, Tennessee, and Kentucky. All these companies were consolidated, in 1926, under the name of the Blue Diamond Coal Company, and Mr. Bonnyman was made President of the Consolidated Company, which has more than \$6 000 000 invested and a capacity of 3 500 000 tons per yr.

Although James Bonnyman began his career as an Engineer and had connection with or supervision over engineering work all the forty years of his business life, his principal experience was as a financiar and an executive.

He was considered by all who knew him to be a man of great courage, force, and ability, combined with a gentle and kindly personality. Making true, loyal, and sincere friends, particularly with people working under him, was an outstanding characteristic. In religion, he was a Roman Catholic.

Mr. Bonnyman was married at Bainbridge, Ga., on December 14, 1905, to Allie Golden Cliette. He is survived by Mrs. Bonnyman and his children, James Bonnyman, Jr., and Mrs. Theodore Irving (Mary Golden Bonnyman) Reese.

He was a member of the Cincinnati Country Club and the Queen City Club, of Cincinnati.

Mr. Bonnyman was elected a Member of the American Society of Civil Engineers on April 2, 1912.

CHARLES BROSSMAN, M. Am. Soc. C. E.[1]

DIED JUNE 30, 1937

Charles Brossman, the son of Charles G. E. and Emily (Kohler) Brossman, was born in Philadelphia, Pa., on January 17, 1877. After his graduation from the Philadelphia Manual Training School, he entered the employ of Willyoung and Company, of Philadelphia, makers of scientific instruments and apparatus. His next work, with the Baldwin Locomotive Works, in Philadelphia, was interrupted by service in the Spanish-American War with the Puerto Rican Expedition as a member of the First Troop, Philadelphia City Cavalry.

In 1900, Mr. Brossman moved to Indianapolis, Ind., where he was engaged in the design of filtration plant and pumping equipment for the Indianapolis Water Company. At the same time, through association with the Dean and Shibley Company, he had a responsible part in the construction of the filtration plant in Washington, D. C.

Mr. Brossman, in 1904, entered the private practice of engineering and opened a Consulting Office in Indianapolis, with Mr. R. P. King, under the firm name of Brossman and King. This partnership was dissolved in 1907, and Mr. Brossman continued the consulting practice in his own name. His engineering work centered in the Middle West, notably in Michigan, Illinois, Iowa, Ohio, Kentucky, and Indiana.

---

[1] Memoir prepared by H. S. Morse, M. Am. Soc. C. E.

As with most young practicing engineers, his earlier work had considerable variety, including design and supervision of construction of factory buildings, asphalt plants, street improvements, and heating and power plants. Gradually, however, as his reputation grew, he specialized in water supply and sewage disposal for cities, towns, and institutions. His career was stopped at its peak by his sudden and untimely death on June 30, 1937.

As is usual with successful engineers, Mr. Brossman's activities were extended in generous service to his profession. In addition to his membership in numerous technical and business organizations, he was Secretary of the Indiana Engineering Society for twenty years, and, later, was President of that organization. He served as President of the Indiana Section, American Society of Mechanical Engineers; Treasurer of the Indianapolis-Lafayette Section, American Institute of Electrical Engineers; President of the Scientech Club of Indianapolis; and President of the Indiana Sanitary and Water Supply Association (later, the Indiana Section of the American Water Works Association). At the time of his death, he was President of the Indiana Section, American Society of Civil Engineers.

Not satisfied with his contributions to the up-building of his profession, Mr. Brossman was the author of many articles in the public and technical press, in the publications of the organizations of which he was a member, and of numerous papers presented at engineering meetings. The Ohio Valley floods in January, 1937, added to his burden of engineering engagements, but he still found time to prepare articles for publication on flood-control measures in Indiana.

His interests were by no means confined to his professional work, but were carried on into the life of the community in which he made his home. At the time of his death, Mr. Brossman was Chairman of the Boys Work Committee of the Indianapolis Rotary, an incident in his busy life, but in itself indicative of his widespread interest in the people about him.

Socially, he was a genial companion, possessed of a rare sense of humor and full of sparkling fun. A man of unimpeachable integrity, his code of professional ethics was exceptionally high. His varied interests and his willingness to serve made him an unusually active and useful citizen, as well as an honor to his profession.

In the fall of 1903, he was married to Mary Edith Dean, of Indianapolis. His widow and three children, Charles Dean Brossman, Mrs. Francis (Brossman) Meyer, and Mrs. Frank (Brossman) Parish, survive him.

Mr. Brossman was elected a Member of the American Society of Civil Engineers on June 18, 1918.

MELVIN DAVID CASLER, M. Am. Soc. C. E.[1]

DIED JANUARY 27, 1937

Melvin David Casler was born at Bordentown, N. J., on September 23, 1881, the son of Melvin Lipe and Carrie (Fiske) Casler, of German ancestry.

---

[1] Memoir prepared by Arthur V. Ruggles, M. Am. Soc. C. E.

Following his early education in the public schools of Fort Plain, N. Y., he entered Union College, at Schenectady, N. Y., in 1902, and was graduated in 1906 with the degree of Bachelor of Science in Civil Engineering.

Before entering college, Mr. Casler was employed from June, 1899, to January, 1900, as Machinist and Draftsman by the Marvin and Casler Company, of Canastota, N. Y., the firm of which his uncle, Herman Casler, was a member. From January, 1900, to May, 1902, he was engaged in office and factory management for S. E. Trumbull, of Johnstown, N. Y., and from May to September, 1902, was Engineering Draftsman for H. C. Allen, of Syracuse, N. Y.

Throughout his college course, Mr. Casler continued outside employment, during the college terms as well as the summer vacations. From September, 1902, to June, 1903, he assisted his father, Melvin L. Casler, of Fort Plain, N. Y., on surveying and drafting, and from June to September, 1903, he was in charge of surveys and maps, and drainage investigations for Eugene R. Smith, of Islip, N. Y. From September, 1903, to June, 1904, he was engaged on road and pavement drawings for C. W. Trumbull, of Schenectady, and from June to September, 1904, he was Chief of Party on drainage surveys and investigation of flood control for the New York State Court of Claims. Throughout his third year at Union College (September, 1904, to May, 1905) Mr. Casler was employed by that College as Engineering Instructor and the following summer (May to October, 1905), he was in charge of construction work costing $670 000 on Contract 3 of the New York State Barge Canal, at Fort Miller, N. Y. During his Senior College year, he was employed by the late Olin H. Landreth, M. Am. Soc. C. E., of Schenectady, on sewer work and maps, and also served as Instructor in Mathematics and Physics at the Schenectady High School.

After his graduation from Union College, he returned to the New York State Barge Canal, where, from July to November, 1906, he was in charge of surveys of alternative routes and studies of drainage problems and economical canal location, and from November, 1906, to May, 1907, on the design of locks and dams, and on problems of rainfall, run-off, and storage.

In May, 1907, Mr. Casler began a period of service which lasted until September, 1916, with the Board of Water Supply of the City of New York. Until March, 1910, he was Assistant Engineer Designer on structures for the Ashokan Reservoir, Catskill Aqueduct, and Hill View Reservoir. From March, 1910, to July, 1912, he was Assistant Section Engineer, and from July, 1912, to September, 1916, Section Engineer, in charge of construction, in Yonkers, N. Y., of Section 2, Hill View Division, which included Hill View Reservoir and appurtenant structures, costing $3 400 000.

He was employed from September, 1916, to June, 1918, as Designing Engineer by the Bronx River Parkway Commission, at Bronxville, N. Y., and from June to October, 1918, he was engaged on the installation of the H. L. Gantt Industrial Management Methods and Cost Accounting Systems, in the United States Naval Aircraft Factory, at Philadelphia, Pa., and other manufacturing plants.

From October, 1918, to November, 1919, he was with the National Conduit and Cable Company, of Hastings, N. Y., as Management Engineer, and from November, 1919, to August, 1921, as Production Manager for the Watson Truck Company, of Canastota, N. Y.

Mr. Casler was again in the employ of the City of New York from August, 1921, to June, 1924, serving as Assistant Engineer with the Board of Estimate and Apportionment in charge of a force of designers and draftsmen on the preparation of preliminary designs and estimates and contract drawings for the proposed freight and passenger subaqueous tunnel between Staten Island and Brooklyn, N. Y. Mr. Casler was in direct charge of the design of a considerable part of this tunnel and personally developed the theoretical stress analysis for the shield tunnel section.

From June, 1924, to September, 1929, he was Designing Engineer for the Hudson River Regulating Board, at Albany, N. Y. As such, he had charge of the preparation of plans and specifications for the Conklingville Dam and appurtenant structures. This dam was built to create the Sacandaga Reservoir on the river bearing that name, and serves both to regulate the flow of the Hudson River, to which the Sacandaga is tributary, and to develop power at the Conklingville Dam.

He was Senior Assistant Engineer, from September, 1929, to April, 1930, with the North Jersey District Water Supply Commission, at Newark, N. J., on studies, estimates, and a report on projects for additional water supply for the North Jersey District.

From April, 1930, until his death, Mr. Casler was Assistant Engineer with the Port of New York Authority on the design of the Lincoln Tunnel—the shield-driven vehicular tunnel now (1937) under construction under the Hudson River on line with West 39th Street, in New York City.

Mr. Casler was proficient in both the design and construction of engineering works and as engineer in charge carried through successfully important work of both kinds. He had unusual mathematical ability and most of the articles which he contributed to engineering publications were of a mathematical nature. A book which he published in 1915 was entitled "Simplified Reinforced Concrete Mathematics" His work was invariably noted for painstaking thoroughness, and his associates knew that any task which he undertook would be carried through faultlessly.

He was quiet and unassuming, at the same time genial and sincere. He was a man of the highest character and a true friend to many who knew him. Besides his professional activities, his interests were mainly in his family, his home in Mount Vernon, N. Y., and his summer camp near the Upper Hudson River. He was a member of the Madison Avenue Presbyterian Church, of Albany, N. Y., of the Masonic Lodge of Canastota, N. Y., and of Sigma Xi Fraternity.

In 1907, the year following his graduation from Union College, Mr. Casler was married to Edna Lucy Greene, of Fort Plain, N. Y. Mrs. Casler and an uncle, Herman Casler, of Canastota, N. Y., survive him.

Mr. Casler was elected an Associate Member of the American Society of Civil Engineers on September 5, 1911, and a Member on April 19, 1916.

GEORGE CHAMPE, M. Am. Soc. C. E.[1]

DIED AUGUST 24, 1937

George Champe was born at Dublin, Ind., on July 29, 1868, the eighth child of Dr. George Washington and Elizabeth (Nation) Champe. His father was descended from John Champe, a Revolutionary War veteran, whose daughter married George Washington's brother. His childhood was spent in the Village of Dublin, where he received his preliminary education at the Grade School, and his preparatory education at the Dublin High School. In 1888, he was graduated from Dublin High School with scholarship honors in mathematics. In 1889, at the age of 21, he was matriculated at Indiana State University, Bloomington, Ind., and was graduated from that institution in June, 1893, with the degree of Bachelor of Arts in Mathematics. As a student, he assisted in the planning of the campus of this young university. His college course was interrupted in 1890 for six months when he was engaged as a Computer for the Missouri River Commission.

Immediately upon Mr. Champe's graduation from Indiana State University, he became City Civil Engineer of Bloomington, and continued in that position until the spring of 1895, when he resigned to accept the position of Assistant City Civil Engineer of Indianapolis, Ind. He then took a term course in engineering subjects at Rose Polytechnic Institute, at Terre Haute, Ind., and also at Indiana University, returning in 1896 to Bloomington as City Civil Engineer and remaining in that capacity until June, 1900.

During his early years of engineering practice, George Champe often expressed a desire to locate in Toledo, Ohio. In the early part of 1900, he had occasion to make a business trip to Toledo, and he was so greatly impressed with the geographical facilities and transportation opportunities of the city that he resolved to accept a position with Carlin Brothers, builders of railroads, and locate there. Accordingly, in June, 1900, he and Mrs. Champe moved to Toledo, where he established a private consulting office. This was during the time of rapid expansion of the electric interurban railways, and his principal energies were directed into that field. He was associated with the design of many of the sixteen electric railways which radiated from the City of Toledo like the spokes of a wheel from the hub; in particular, he was largely responsible for the design of the Toledo and Western Railroad, the Toledo and Indiana Railway, and the Toledo, Fostoria and Findlay Railway. In the course of this railway work he made many friends in the cities and villages which were tapped by these carriers, and these friendships later were especially valuable because of the era of hard-surface pavement construction that was ushered in following the advance of the railways. More than 275 pavements in approximately 50 communities in Ohio, Michigan, and Indiana, to the value of more than \$3 000 000, were designed and supervised by him.

---

[1] Memoir prepared by Carleton S. Finkbeiner, Assoc. M. Am. Soc. C. E.

In this period also, there was a rapid increase in the demand for water-works and sewerage facilities in the outlying municipalities, and George Champe was responsible for the design of more than twenty-five original water-works systems and numerous other water-works improvements, representing expenditures in excess of \$2 000 000. Sewerage systems, sewage-treatment plants, and some power plants, including hydro-electric ones, were built under his design, representing investments of more than \$1 000 000. Bridges also came under his planning, and he was Associate Engineer on the \$3 000 000 High-Level Bridge at Toledo.

During the last ten years of his life, George Champe became more and more identified with civic movements in his home city, becoming Chairman of the Lucas County Planning Commission, Vice-Chairman of the City Plan Commission, and member of the Port Commission and the Mosquito Elimination Committee. In 1931, he volunteered his service in the design of the airport runways at the Toledo Transcontinental Airport.

He was a member and Elder of the Collingwood Avenue Presbyterian Church, member of the Masonic Order, Rotary Club of Toledo, American Water Works Association, Toledo, and the Ohio Society of Professional Engineers. From 1933 to his death, he was a part-time Instructor at the University of Toledo in Sanitary Engineering.

The character of George Champe was firmly molded along the lines of absolute integrity and devotion to his profession. All phases of engineering struck a responsive chord in him because his interests were manifold. His many transactions with political sub-divisions had developed a very fine flair for diplomacy.

On November 17, 1897, Mr. Champe was united in marriage to Harriett May Noble, of Indianapolis. Surviving him, in addition to Mrs. Champe, are two daughters, Mrs. Dorothy C. Longnecker and Elizabeth Champe; and two sons, Willard and Carlton.

Mr. Champe was elected a Member of the American Society of Civil Engineers on December 4, 1922.

ARNOLD GOODWIN CHAPMAN, M. Am. Soc. C. E.[1]

DIED JUNE 3, 1937

Arnold Goodwin Chapman was born in Guilderland, N. Y., on July 23, 1884. He was the son of George Ashley and Ida (Goodman) Chapman. His preliminary education was obtained in the public schools in Albany, N. Y., on completion of which he entered Union College, at Schenectady, N. Y., from which he was graduated in 1906 with the degree of Bachelor of Engineering.

---

[1] Memoir prepared by Dwight B. La Du, M. Am. Soc. C. E.

The greater part of Mr. Chapman's professional life was spent in public service. Immediately following his graduation from Union College he entered the Department of the State Engineer and Surveyor of the State of New York as a Chainman, where he served continuously until 1915. During this period he was promoted through the grades of Assistant Engineer, Assistant Deputy State Engineer, and Deputy State Engineer, which position he held from 1912 to 1915 under the late John A. Bensel, Past-President, Am. Soc. C. E. The scope of Mr. Chapman's engineering experience during these nine years was broad, including highway construction, and the many and varied problems which presented themselves in connection with the design and construction of the Barge Canal System, the greater part of which was built during this period.

Mr. Chapman retired as Deputy State Engineer in 1915, and entered private practice as a Consulting Engineer which he continued through 1922. While thus engaged, he was connected with many important engineering works involving the design and construction of flood-control projects, municipal construction projects, and various other engineering activities.

In 1923, he returned to the State service as Deputy State Engineer under Dwight B. La Du, M. Am. Soc. C. E., and occupied this position until the end of 1924. During 1925 and 1926 he was retained by the Department of Public Works of the State of New York, as Supervising Engineer in charge of the Hornell and Canisteo Flood Abatement Projects, and during 1927 as a general Engineering Consultant.

In 1928, Mr. Chapman was appointed Chief Engineer of the Albany Port District Commission and served as such until 1936. He prepared the comprehensive plan which was followed in the building of the Port and was in charge of the design and construction of the Port Terminal facilities, involving the dredging of nearly 4 000 000 cu yd of material, the reclaiming of 300 acres of land, the construction of dock walls extending more than 5 000 ft, the largest single unit grain elevator in the world, storage sheds, streets, sewers, railroad facilities, and, in fact, everything that goes to make up an inland port equipped to handle ocean-going traffic.

While his work in connection with the Barge Canal and the many other projects on which he was at one time engaged was noteworthy, the contribution he made as an Engineer to the Port of Albany was his outstanding engineering achievement, and his name will be inseparably linked with this development for all time.

In 1936, he resumed private practice as a Consulting Engineer in Albany, and was carrying on such practice at the time of his death. He was also serving as Manager of the New York State Waterways Association and as Executive Secretary of the New York State Society of Professional Engineers.

The professional societies with which he was affiliated, included the Albany Society of Civil Engineers, New York State Society of Professional Engineers (of which he was a Past-President), and the National Society of Professional Engineers. His college fraternities were Psi Upsilon and Sigma Xi. His clubs in Albany were Fort Orange, University (of which he was President at the time of his death), and the Albany Country Club. Mr.

Chapman was a Mason, Knight Templar, and Shriner, and a member of the First Presbyterian Church, of Albany.

On June 12, 1912, he was married to Marjorie A. Nead, who, with three children, Arnold G. Chapman, Jr., Marjorie Chapman, and Carol Chapman, survives him.

Due to his many years of outstanding public service, both to his State and City, Mr. Chapman had established a reputation as an Engineer which extended beyond the bounds of his own City and State. During the later years of his life, he gave unselfishly of his time and energy to the advancement of the standing of the engineer through his advocacy of licensing the practice of engineering and the fixing of minimum requirements which must be met before one may call himself an engineer.

The death of Arnold Goodwin Chapman marked the passing not only of a capable engineer, but also of a man who was beloved by all whose good fortune it had been to know him.

Mr. Chapman was elected a Junior of the American Society of Civil Engineers on July 1, 1909; an Associate Member on April 30, 1912; and a Member on January 20, 1920.

FRANK DAVID CHASE, M. Am. Soc. C. E.[1]

DIED JULY 23, 1937

Frank David Chase was born in Riverside, Ill., on August 2, 1878, the son of David Fletcher Chase and Emily Frances (Tabor) Chase. He was a descendant of old American families, and in the paternal line traced his ancestry from Thomas Chase, who came to America about 1638.

Frank David Chase received his early education at the Evanston (Ill.) Township High School, and was graduated in 1901 from the Massachusetts Institute of Technology, in Boston, Mass., with the degree of Bachelor of Science in Civil Engineering. After his graduation he spent four years in the Engineering Departments of the Minneapolis and St. Louis Railroad Company and the Chicago and Alton Railroad Company.

From 1905 to 1907, he was employed by the Leonard Construction Company as Superintendent on building work, and during the following six years he held the position of Architect, first for the Illinois Central Railroad Company and then for the Western Electric Company, with headquarters in Chicago Ill. In 1913, he organized his company of Frank D. Chase, Incorporated Engineers and Architects.

Soon after beginning his active career, he became impressed with the possibilities of industrial engineering, the design of manufacturing plants, and other large business and industrial structures, with a view to the greatest efficiency in production and the most economical utilization of space, and decided to become a Specialist in this field.

---

[1] Memoir prepared by Harry H. Hadsall, M. Am. Soc. C. E.

As President of the Company, he directed its management, and under his personal leadership its business developed very rapidly. His services were retained by railroad companies, large industrial corporations, and newspapers throughout the United States, and the ideal utility of his designs, approved by the test of practical operation and experience, won him a notable reputation.

Mr. Chase designed, among others, the plants of the *St. Louis Star-Times,* in St. Louis, Mo., *The Oklahoman,* in Oklahoma City, Okla., and the *Milwaukee Journal,* in Milwaukee, Wis., the latter of which has been called one of the finest newspaper plants in America.

As Architect and Engineer of his Company he designed and constructed more foundries than any other consultant in the United States. He was also retained on plant construction in Europe, and executed a large industrial contract in Soviet Russia. He did not confine his efforts solely to industrial projects, however, and designed a number of mercantile buildings in the Loop District, in Chicago, including the 23-story building, at 100 West Monroe Street, the 16-story building, at 173 West Madison Street, and the 10-story Starck Building. He also designed the Chicago Memorial Hospital and the South Chicago Community Hospital.

Mr. Chase, who was active until his death, was an acknowledged authority in his chosen field. His professional standing was reflected in his election as President of the Western Society of Engineers, serving from June 1, 1931, to June 1, 1932. In 1933 and 1934 he was Executive Director and Chief Engineer of the Civil Works Administration for the State of Illinois, and Chief Engineer of the Illinois Relief Commission. In 1936, he served as Chairman of the Washington Award Commission, and presided at the presentation of the Award for that year to Charles Kettering, M. Am. Soc. C. E., the ceremonies being broadcast by radio.

Mr. Chase was formerly a member of the Engineers Club, of New York, N. Y., the Engineers Club, of Chicago, the Barrington Hills Country Club, and the Union League and the University Club, of Chicago. He enjoyed outdoor life and travel, and spent much of his spare time in the West, particularly in Arizona and New Mexico, where he frequently went on camping trips to study the relics of earlier Indian culture.

He was married, in 1927, to Cecile Chambers, of Chicago, who, with one daughter, Eloise, survives him. His brother, Al Chase, is the Real Estate Editor of *The Chicago Tribune.*

Mr. Chase was elected an Associate Member of the American Society of Civil Engineers on June 30, 1910, and a Member on April 2, 1912.

JOHN CARROLL CHASE, M. Am. Soc. C. E.[1]

DIED APRIL 15, 1936

John Carroll Chase was born on July 26, 1849, at Chester, a town in the southern part of New Hampshire, not far from Manchester, the only child of

---

[1] Memoir prepared by C. Frank Allen, M. Am. Soc. C. E.

Charles and Caroline (Chase) Chase. He was of the eighth generation in descent on his father's side from Aquila Chase who settled in 1640 at Hampton, at that time a part of the Massachusetts Bay Colony. His mother also was descended in the eighth generation from the same Aquila Chase. A Chase family in Chesham, England, has in its records the name, Aquila, which caused some claim that the American family came from that town, but John Carroll Chase, himself an eminent authority in such matters, following researches in England, states that it "may be descended from the Chesham family, but our researches fail to show such a connection." The ancestors of John Carroll Chase soon moved from Hampton to Newbury, Mass., and, later, to Chester, where he was born.

Brought up on a farm, he attended the local district school and, later, Chester Academy. Afterward, he attended Pinkerton Academy, in Derry, N. H., from which he was graduated in 1869. After a year of teaching, he entered the Massachusetts Institute of Technology, at Boston, Mass., as a member of the Class of 1874, and took up the study of Civil Engineering. His grandfather, Benjamin Chase, had acquired a mastery of mathematics, geometry, trigonometry, surveying, navigation, and astronomy, his proficiency in the latter allowing him to predict eclipses well in advance. He also prepared a map of the township of "Old Chester." He is said to have possessed unusual mechanical skill and was much in demand as a millwright throughout neighboring towns in New Hampshire and Massachusetts. In 1871, after spending a year at the Massachusetts Institute of Technology, young Chase was married, and his studies at the Institute of Technology were discontinued, but his purpose to become a Civil Engineer was not quenched; his inheritance perhaps asserted itself.

His first employment in Civil Engineering was in the office of Joseph B. Sawyer, in Manchester. More importantly, for about four years, he served as an Assistant Engineer on the construction of the water-works for Manchester. Following this, he was Assistant Engineer on the construction of the conduit of the Sudbury River System of the Boston (Mass.) Water Supply, and, afterward, as Assistant Engineer on the elevated railway of New York, N. Y.

In 1880, failing to secure work in engineering, Mr. Chase filled a Civil Service position under the Federal Government and became Assistant Cashier in the Naval Office. Late in 1881, he resigned to accept the position of Superintendent and Engineer of the Clarendon Water-Works, at Wilmington, N. C., of which later he became Chief Engineer. During his term of service in Wilmington, he occupied as well the position of City Surveyor and also became a member of the Wilmington Board of Health. Mr. Chase was also, for four years, the Engineer Member of the State Board of Health and rendered valuable service in this capacity; this was in the early days of sanitation in North Carolina. His activities, however, were not confined to Wilmington, for during his residence there, he was engaged in general practice in North Carolina, South Carolina, and Georgia. During this time he designed and constructed the water-works and sewerage systems for Albany, Ga.

Although a Northern man in a Southern community during the reconstruction period, he promptly made many friends in Albany, and the fact that he was continuously acceptable was alike creditable to those with whom he became associated, as well as to Mr. Chase himself.

After more than twenty-four years in engineering activities, Mr. Chase resigned in 1897 to return to Derry to enter the employ of his uncle, Benjamin Chase, Jr., in a business which, in 1907, was incorporated as the Benjamin Chase Company, of which he was General Manager and Treasurer. Subsequently, he became President, an office which he held for more than twenty years prior to his death. The business is that of manufacturing nationally known specialties in wood, among them tree and pot labels used by nursery men and florists. Probably two-thirds of all such labels that have been used in the last thirty years in the United States and Canada, have been made by this Company. Its administration was successful and was continued by Mr. Chase as his main or sole business interest to the time of his death. However, the attention he found it necessary to give to it did not prevent him from giving much time to many interests of a varied sort.

While still in the South, before his return to Derry, Mr. Chase was elected a Trustee of Pinkerton Academy, being the first alumnus to be so chosen. Soon after his return to Derry, he became Secretary of the Board and Chairman of the Executive Committee of the Academy, and was recognized as its most influential member. He was also Secretary of the Alumni Association. He devoted considerable time to a study of its records and compiled many interesting data with relation to it. Mr. Chase was an active helper of the Congregational Church, at Derry, and the "mainspring" of the Men's Club. He was a Trustee and Treasurer of the Taylor Library of that city, and also President of the Nutfield Savings Bank. He was regarded as one of the leading citizens of Derry; undoubtedly, he was the most widely known.

Although the practice of his profession was laid aside, his interest in engineering persisted. Aside from continuance in the Society, he enrolled as a member of the Northeastern Section, and also maintained membership in the New England Water Works Association (of which he had become the senior member), and in the Boston Society of Civil Engineers. He was well-nigh a constant attendant at the dinners and meetings of these societies. He also attended many of the Annual Meetings and Conventions of the American Society of Civil Engineers. Equally, he attended the meetings of the Alumni Association of the Massachusetts Institute of Technology and of its Alumni Council. It is of interest to note that although he attended Technology only one year, he was the representative, on the Council, of his Class of 1874. He seemed to possess something of the "gang" instinct, a get-together habit, as appears more fully later, so that his attendance at these and other meetings could perhaps be regarded in his later years in the light of recreation. Due to his interest in engineering, he was an early member, as well as a Fellow, of the American Public Health Association.

In fraternal organizations, Mr. Chase was active in Free Masonry in which his memberships extended from Master Mason to Knight Templar, and he was elected to the highest offices in his Chapter, his Council, and his Commandery. He was Past Deputy Grand Commander and member of the Grand Commandery of Knights Templars of North Carolina and, frequently, went South to attend its Annual Conclave. He was a member and Past Patron of the Order of the Eastern Star. He held the highest office in the Supreme Council of the Royal Arcanum. He was a member, too, of the Independent Order of Odd Fellows for more than fifty years.

His clubs included the University, City, and Appalachian Clubs, of Boston, the Technology Faculty Club, of Cambridge, Mass., the Technology Club, of New York, and the University Club, of San Diego, Calif.

His interests in another direction led him to become a member of a number of historical and hereditary patriotic organizations, among them the Society of Colonial Wars in the Commonwealth of Massachusetts (Deputy Governor General), the Society of Colonial Wars in the State of New Hampshire, the Massachusetts Society of Sons of the American Revolution (Member of the Governing Board), the Bunker Hill Monument Association (Director), the Governors and Company of the Massachusetts Bay in New England, the New Hampshire Historical Society, the Piscataqua Pioneers (Vice-President), the Bostonian Society, and the Society for the Preservation of New England Antiquities.

Membership in these societies was quite in line with what appears to have been his main interest for many years, membership in the New England Historic Genealogical Society. He became a member in 1899, soon after his return from the South and later was made a life member. In 1921, he became its President, an office which he filled until his death. In this Society he also was a member of a newly established class designated as Pilgrim Tercentenary Member, receiving the certificate stamped No. 1. Three years after he became the President of this Society, on the wall of the stair hall of the New England Historic Genealogical Society's house, in Boston, Mr. Chase placed a tablet, surmounted by the representation of a ship of early Colonial days under full sail, and bearing this inscription: "Aquila Chase Mariner 1618 1670 Hampton N H 1640 Newbury Mass 1646 By old repute the first Pilot at the mouth of the Merrimack River Erected by his descendant John Carroll Chase 1924." To his genealogical work he brought the accurate and honest mind of a trained engineer. The last public function which he was able to attend was in January, 1936, when he presided as Deputy Governor of the Society of Colonial Wars of Massachusetts at a meeting of that Society.

Whether or not there was an element of cause and effect in it, it happened that coincident with his joining the New England Historic Genealogical Society, Mr. Chase, as one of the Founders, was instrumental in the formation of the Chase-Chace Family Association of which he became the first President. Later, in 1928, he published, with the co-operation of George Walter Chamberlain, a volume of 600 pages entitled "Seven Generations of Aquila and Thomas Chase," a book presenting a broad survey of the Chase family in America and his family history. In 1926, he published a book of about 550 pages entitled "History of Chester, New Hampshire, Including Auburn, a Supplement to the History of Old Chester," the latter having been written by his grandfather. He was also author of "The Descendants of William Chase." He was a frequent contributor to newspapers and society journals, of articles of both civic and professional quality. As late as March, 1935, in his capacity as President of the New England Historic Genealogical Society, he made an address on "Ninety Years of the Corporate Existence of the Society," which was duly published in the "Register" of the Society.

Mr. Chase was kindly by nature, helpful to others in many ways, and generous beyond his means, some thought, as he was not a wealthy man. Although unassuming in habit, unselfish, and not contentious, that Mr. Chase possessed high qualities of leadership is abundantly evident from the prominence accorded him in various societies and organizations of which he was a member. At meetings of such bodies, his presence was familiar and welcome. He readily made friends, young as well as old, and his friendships were many. His trips to the Pacific Coast became an annual circumstance rather than an event, and it is interesting to note that he maintained membership in the University Club of far-off San Diego. These trips were often in the interests of his Benjamin Chase Company at some convention of the nursery men of that section, when he was greeted as "Uncle John," or at times at meetings of Technology Alumni who were glad to secure fresh news from their Alma Mater.

His frequent transcontinental trips by varying lines of travel were often interrupted en route, giving him opportunity to know more of the United States and also to make contact with genealogical societies and individuals interested in genealogy in other States. It was not uncommon for him to go long distances out of his direct route in order to call on some friend whose acquaintance he had made in earlier travels.

As stated in a memoir [2] published by another Society,

> "The cosmopolitanism of this man greatly impressed me at the time his associates gave a dinner in honor of the eightieth anniversary of his birth. The response which it evoked in Wilmington, N. C., in San Diego, Calif., and in Vancouver, B. C., would have led one to believe that he was a resident of each of these communities, quite as much as of Derry, N. H., where his business interests lay, or of the adjoining town of Chester, where he was born, or of Brookline, where he spent his last eight winters. He had entered into the life of all these communities."

The same memoir, referring to his journey to Europe in 1932 in his eighty-fourth year, recites that,[3]

> "* * * on such journeys he visited the great engineering projects which might be in the making, observing them with a keen professional insight and interest. In this way be kept fully abreast of the progress of civil engineering, for he always remained an engineer at heart, even though engrossed in the problems of business or the preparation of his books and papers dealing with historical research."

---

[2] *The New England Historical and Genealogical Register*, July, 1936, p. 221, Line 46, to p. 232, Line 4.

[3] *Loc. cit.*, p. 22, Line 34 to Line 39.

Quoting from another memoir,[4]

"New England to the core, by descent and temperament, Mr. Chase lived an abundant life, active, keen of mind, friendly, of broad cosmopolitan interests and of sterling character. His life may well have been guided by the Chase motto, 'Ne Cede Malis.'"

Mr. Chase was married in 1871 to Mary Lizzie Durgin, of West Newbury, Mass., who died in 1927, following a protracted illness. In 1928, he was married to Florence Anne Buchanan, of Brookline, Mass., who survives him. He is also survived by two daughters, Carolina Louise, married to Dr. Raffael Lorini, formerly of Coronado, Calif., and for many years a prominent physician there, but now retired; and Alice Durgin, married to Professor Samuel Cate Prescott, Dean of Science at the Massachusetts Institute of Technology.

Mr. Chase was elected a Member of the American Society of Civil Engineers on March 1, 1893.

MELVILLE FISK CLEMENTS, M. Am. Soc. C. E.[1]

DIED JUNE 8, 1937

Melville Fisk Clements was born at What Cheer, Iowa, on March 13, 1875, the son of Wilbur F. and Rebecca (Fair) Clements. After completing his early education in the public schools, he entered the University of Iowa, at Iowa City, Iowa, from which he was graduated, in 1899, with the degree of Bachelor of Science. Later, he did post-graduate work at George Washington University, at Washington, D. C. In 1904, he received the degree of Civil Engineer from the University of Iowa.

Previous to completing his course in the University of Iowa, Mr. Clements was employed for a short period as a Draftsman in the Topographer's Office, in the Post Office Department, at Washington, D. C. Following his graduation in 1899, he was employed as Assistant Engineer on Maintenance on the Burlington, Cedar Rapids and Northern Railway until 1902, when he joined the Engineering Department of the Chicago, Rock Island and Pacific Railway Company, where he served as Chief Draftsman in the Maintenance-of-Way Department, as a Designer in the Bridge Department, and as Assistant Division Engineer on Maintenance. In 1906, he joined the Clinton Bridge and Iron Company, at Clinton, Iowa, and was in charge of design and shop inspection.

In 1907, Mr. Clements began his connection with the Northern Pacific Railway Company, which continued until his death. His first work was in the Bridge Department as a Designer. Following this, he was Assistant Engineer on Construction for several years, handling many important projects, including heavy bridge construction, reconstruction of branch lines, tunnel and subway work, and a large grade-separation project, in Spokane,

---

[4] *Journal*, New England Water Works Assoc., December, 1937, p. 481.

[1] Memoir prepared by M. W. Beach, Bridge Engr., N. P. Ry., St. Paul, Minn.

Wash. In 1916, he was made Bridge Engineer, with headquarters at St. Paul, Minn., which position he held at the time of his death.

For several years, Mr. Clements had been retained as Consulting Engineer on important deep foundation work. He invented the Sand Shell Island Method of sinking caissons, which consists essentially of the erection and sinking of a circular steel shell which is filled with sand to the water surface, and in which the ordinary practice of constructing and sinking the caisson is followed. This method was followed successfully under his direction on two important foundation projects, the Suisun Bay Bridge, on the Southern Pacific Railway, at Benecia, Calif., and the Huey P. Long Memorial Bridge, at New Orleans, La.

Throughout his life Mr. Clements was known and admired for his fairness, and for his friendly interest in the problems of others. He was endowed with a keen intellect, broad vision, and a pleasing personality. He was a man of sterling character and was liked by all who knew him.

He was a member of Sigma Xi, the St. Paul Engineers Club, the American Railway Engineering Association, the St. Paul Chapter of the American Interprofessional Institute, and the St. Paul Athletic Club. He was an Elder of the House of Hope Presbyterian Church, of St. Paul, Minn., in which he had a deep interest.

In 1900, he was married to Minnie Coover, who survives him; also surviving are his mother and two sisters.

Mr. Clements was elected a Member of the American Society of Civil Engineers on September 2, 1914.

CLARKE PELEG COLLINS, M. Am. Soc. C. E.[1]

Died September 19, 1937

Clarke Peleg Collins was born on December 14, 1868, at Narragansett, R. I., the son of Peleg Gardner and Mary Winslow (Hawkes) Collins. The family was a member of the Society of Friends. His forefathers, coming from England, settled in Lynn, Mass., in 1635.

Mr. Collins was graduated from Friends School (later Moses Brown School), at Providence, R. I., with the Class of 1887. Although he was able to attend only one year at Rensselaer Polytechnic Institute, at Troy, N. Y., he gained a thorough knowledge of his profession through constant study and practical experience. He completed the Civil Engineering Course and Mining Course of the International Correspondence School of Scranton, Pa. He also held a certificate of proficiency from the American School of Correspondence, of Chicago, Ill., in Hydraulic and Sanitary Engineering. He studied municipal and sanitary engineering under the late Samuel M. Gray, M. Am. Soc. C. E., Consulting Engineer, of Providence; hydraulic and sanitary engineering under E. J. McCaustland, M. Am. Soc. C. E., of Cornell University, at

---

[1] Memoir prepared by Thomas S. Lang, M. Am. Soc. C. E.

Ithaca, N. Y.; mining engineering and geology under John Fulton, Consulting Mining Engineer and Geologist, of Johnstown, Pa.; and bridge engineering under Emil Goldstein, of the American Bridge Company, in Johnstown. In addition to technical courses studied under the direction of others, Mr. Collins averaged two hours a day in the study of technical subjects for a period of ten years after leaving Rensselaer Polytechnic Institute.

In 1888, Mr. Collins joined the Staff of Mr. Gray, then City Engineer of Providence, in the Park and Highway Department. He continued as an employee and student under this well known Engineer until July 28, 1890.

From July, 1890, to August, 1893, he was employed as Assistant Engineer in the Mining Engineering and Survey Department of the Cambria Iron Company, later the Bethlehem Steel Corporation, of Johnstown. He was placed in charge of outside surveys in connection with the mining properties of that Company, railroad maintenance, and extensions. He also assisted in the development of Westmont, an exclusive residential suburb of Johnstown, for the Westmont Land Improvement Company, a subsidiary of the Cambria Iron Company. This work included the grading and paving of streets, installation of sewers, water lines, and gas lines.

In 1893, depression came over the country and in August of that year, while on his honeymoon in Providence, Mr. Collins was notified that the Cambria Iron Company had closed. He immediately went to work in the City Engineer's Office, at Providence, in charge of the construction of a section of the improved sewerage system of that city.

Mr. Collins was recalled by the Cambria Iron Company in 1894, with which he remained until 1900. During the last two years with this Company he was engaged in the investigation of water supply for the Manufacturers Water Company and the Johnstown Water Company, both subsidiaries of the Cambria Iron Company. Following these investigations, he designed the No. 2 Dam on Mill Creek for the Johnstown Water Company. This dam with a capacity of 90 000 000 gal was built according to his plans. He also had charge of the construction of the Otto-Hoffman coke ovens for the Cambria Iron Company.

In 1900, Mr. Collins entered into private practice with offices at Johnstown, conducting business in civil, sanitary, and mining engineering. During his practice in Johnstown, he installed some of the largest mining operations in Western Pennsylvania. He acted as Chief Engineer in charge of making surveys of 40 000 acres of virgin coal in Somerset County, Pennsylvania, for Baltimore interests. Mr. Collins served as Chief Engineer of the Somerset Coal Company, later the Consolidation Coal Company, in charge of twenty-two mining operations in Somerset County. The large plant and development at Ralphton, Pa., was installed under his supervision for the Quemahoning Coal Company of Somerset, Pa.

From 1904 to 1906, he was retained by the United Coal Company, of Pittsburgh, Pa., in charge of the construction of the Jerome Branch Railroad from Hollsopple to Jerome, in Somerset County, as well as the construction of the plant at Jerome, including steel tipple, stone power-house, main and air shaft, 265 ft deep, and miners' houses and store. This plant was considered one of the most modern in Western Pennsylvania. For the Maryland Coal Company, he designed and installed the deep shaft and plant situated at St. Michael, Pa., and also placed in operation for this Company a number of other mines in Pennsylvania, Maryland, and West Virginia.

During his practice in Johnstown he also served as Consulting Engineer for the following: Haws Coal Company, Operators Coal Company, and Citizens Coal Company, all of Johnstown; Federal Coal Company, Black Lick Coal Mining Company, Commonwealth Coal Company, and Maryland Coal Company, of Philadelphia, Pa.; Quemahoning Coal Company, of Somerset; and United Coal Company, of Pittsburgh. This work consisted of examination and valuation of coal properties and reports on virgin coal fields. Reports were made on coal and mineral lands in Pennsylvania, West Virginia, and Canada.

He also executed the following work: Sewerage system for Lilly and Meyersdale, Pa.; drainage system for Hollidaysburg, Pa.; water-works and sewerage system for New Florence and Windber, Pa.

Mr. Collins laid out a number of subdivisions in the vicinity of Johnstown, the most important of which is the attractive Borough of Southmont, which adjoins Westmont and, like the latter, is an exclusive residential suburb of Johnstown.

In 1912, Mr. Collins left his private practice to become Special Engineer for the Berwind-White Coal Mining Company, in which capacity he designed treatment plants for water supply and the disposal of sewage from mining hamlets near Windber.

From 1914 to 1918, he was engaged by the City of Johnstown as Sanitary Engineer. His plans for a sewerage system and disposal works were approved by Mr. Gray, and the late Rudolph Hering, M. Am. Soc. C. E., Consulting Engineer of New York, N. Y. The system was designed to serve a population of 168 000, the estimated cost of which was more than $2 000 000. The work was constructed according to his plans.

From 1918 to 1920 Mr. Collins was in the service of the Government as Senior Engineer with the United States Shipping Board, Emergency Fleet Corporation, at Washington, D. C., and Philadelphia, in charge of sewerage, drainage, and sewage disposal for eighteen housing projects built to serve the merchant shipyards. These projects were situated along the Atlantic Coast from Maine to Florida and in the Central West. During this period he was also delegated to report on the valuation of 30 000 acres of coal land owned by the German Imperial Government, at Farmersville, Ill. This report was made to the late Morris Knowles, M. Am. Soc. C. E., of Pittsburgh, the engineer appointed by the Alien Custodian.

Mr. Collins moved to Clarksburg, W. Va., in 1920, where he was engaged in private practice until March, 1936. During this time he made reports and valuations of properties in Pennsylvania, Maryland, West Virginia, and Kentucky.

In July, 1920, he was engaged by the Mountain Water Supply Company, of Philadelphia, to study the pollution of its dam on Indian Creek, Fayette County, Pennsylvania, by mine drainage. This investigation of streams affected by mine drainage covered a total of 30 687 acres of mined-out areas situated in four counties of Western Pennsylvania. Diagrams were prepared showing the relation between the total flow of mine drainage, in gallons per day, and the total flow of the streams, in gallons per day, at the point where the mine drainage collected, the total sulfates in the mine drainage, and the total sulfates in the stream at the gaging and sampling station. This was the first authoritative report relating to the pollution of streams by mine drainage. Since that time extensive work has been done in the sealing of mines to prevent stream pollution in Pennsylvania, West Virginia, and other coal-producing States.

He was later employed by the Yough Hydro Electric Company to report on the valuation of coal under its property at Swallow Falls, Garrett County, Maryland.

Mr. Collins designed a sewage disposal plant for the Borough of Somerset, and reported on the sewerage system and sewage disposal plant for the City of Spencer, W. Va.

In March, 1927, he was retained by the City of Clarksburg to value the plant and holdings of the Clarksburg Light and Heat Company, for the city's use in presenting its case as protestants before the West Virginia Public Service Commission. He was also employed by the City of Weston, W. Va., in its case against the Weston Water Company, which was presented before the West Virginia Public Service Commission.

In June, 1930, he was retained by the United States Government, Department of Internal Revenue, to testify as to the value of the property of the Quemahoning Coal Company and other coal companies in Somerset County, Pennsylvania, as of 1903.

In 1933 and 1934 Mr. Collins prepared and submitted the necessary data for a $1 400 000 loan and grant from the Public Works Administration for a sewerage system and sewage disposal plant for the City of Clarksburg. This preliminary report was approved by the Public Works Administration, but the loan and grant were not accepted by the city.

In July, 1935, he was retained by the Pennsylvania Coal and Coke Company to testify in its case for reduced freight rates before the Interstate Commerce Commission, at Washington, D. C.

From March, 1936, until the time of his death, he was employed by the Public Works Administration and had just completed supervision of the installation of sewers at Mason and South Parkersburg, W. Va.

Mr. Collins was the author of a number of technical papers: "The Engineer on Development Work,"[2] which was prepared as a helpful hint to young engineers in developing virgin coal fields; "A Comparison of the Combined and Separate Systems of Sewerage;"[3] "The Drainage, Sewerage and Sewage Disposal of Emergency Housing Developments," read before the American Society of Municipal Improvements at its Convention in New Orleans, La., in November, 1919;[4] and "Pollution of Water Supplies by Coal Mine Drainage."[5] In addition, he also made a number of addresses before civic groups in Johnstown and Clarksburg.

---

[2] *Coal Age*, March 9, 1912.

[3] *Municipal Engineering*, October, 1898.

[4] *Proceedings*, Am. Soc. of Municipal Improvements, 1919.

His hobby was writing, and he was the author of several novels, one of which, "In the Wake of the Storm," is a historical novel based on the life of Abraham Lincoln. It was written after several years of research.

As an engineer, Mr. Collins was extremely accurate, painstaking, and thoroughly dependable, possessing a very high conception of proper ethics in his chosen profession. The tireless energy with which he applied himself to his work won him an enviable reputation among his associates.

His philosophy of life is best expressed in a quotation taken from his journal, which he kept from early manhood:

> "A man's life, when weighed in God's balance, is not measured by the wealth he possesses, nor by the number of years he is permitted to live. His span of life may be short, yet the use he makes of the years allotted to him is the true measure of the man."

Mr. William Monroe Davis, of St. Petersburg, Fla., a lifelong friend of Mr. Collins, says of him:

> "From heredity, environment, and training he received all the elements of integrity, honor, and righteousness common to his Quaker ancestors. His life was full, complete, and well rounded out. 'Well done, good and faithful servant of mankind. Enter into thy everlasting reward.'"

In August, 1893, Mr. Collins was married to Leila Thoburn Coleman, of Johnstown, who died in June, 1908. From this union three children survive him: Leon Waterman Collins, Mary Winslow Collins (Mrs. Carl G. Rau), and Helen Thoburn Collins. In August, 1910, Mr. Collins was married to Jessie Ellen Coleman, a niece of his first wife, of Chicago. She and one daughter, Shirley Elizabeth Collins, survive him. He is also survived by one sister, Mrs. William A. Woodward.

He was a member of the American Society for Municipal Improvements (later, the American Public Works Association).

Mr. Collins was elected an Associate Member of the American Society of Civil Engineers on June 4, 1902, and a Member on January 18, 1916.

ELBRIDGE ROBBINS CONANT, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 24, 1937

Elbridge Robbins Conant was born at Acton, Mass., on September 23, 1865. He was the son of Luther and Celeste J. (Robbins) Conant, both of Acton. After finishing his studies at the local schools, he attended the Chauncy Hall School, of Boston, Mass., where he prepared for the Massachusetts Institute of Technology. He completed a four-year course in Civil Engineering at the Institute in 1889, as a Special Student.

---

[5] *Engineering News-Record*, October 18, 1923.

[1] Memoir prepared from information on file at the Headquarters of the Society.

His early work, after leaving the Institute, included a year with the New York and New England Railroad Company, as Instrumentman; a year with the City of Newton, Mass., on the construction of a sewerage system, part of the time as Principal Inspector; and approximately a year with the civil engineering firm of Aspinwall and Lincoln, of Boston, on miscellaneous development projects.

In the fall of 1892, Mr. Conant went South to assume a position with the United States Engineer Department, Southeastern District, with headquarters at Savannah, Ga. He remained with the Department for twenty-one years. Starting as Surveyor or Inspector, he was made a Junior Engineer in 1902, Assistant Engineer in 1903, and from 1904 to 1912, he was Principal Assistant Engineer in full charge of the Sub-Engineer's Offices, at Brunswick, Ga., where he had immediate supervision of the Department's work for ports between Savannah and Fernandina, Fla., and on rivers entering the ocean between these ports. In 1912, his headquarters were transferred back to Savannah.

While with the Engineer Department, Mr. Conant was in immediate charge of important dredging operations and jetty construction at various points, and of the erection of fortifications at Tybee Island and Fernandina. His work also included extensive hydrographic surveys and a large amount of general planning of river and harbor improvement operations.

Mr. Conant left the Government Service in 1913 to become Chief Engineer and Purchasing Officer for the City of Savannah. During the six years that he held this position, he had charge of all public improvements, including the water-works system. He supervised a million-dollar extension of the City's sewerage system, a large amount of pavement construction, and the erection of a "high temperature incinerator plant" for the disposal of the City's garbage. On account of the large quantity of wet garbage, especially in the melon season, this plant involved certain special problems, but these were successfully solved. The operation of the plant attracted wide attention among sanitary engineers at the time.

After leaving the City's service in 1919, Mr. Conant was engaged for more than a year in general consulting work in and about Brunswick, Ga., specializing in paving and road construction. In 1920 he returned to the North. For a year, from March, 1921, to March, 1922, he was Town Manager of Mansfield, Mass., and, later, for a short time, Surveyor (City Engineer) for the Department of Public Highways, in Manchester, N. H. He retired from active work several years ago.

For several years Mr. Conant was a member of the American Society for Municipal Improvements and served as Vice-President of that organization in 1917–1918 and as President in 1918–1919. He was also Chairman of that Society's Committee on Street and Sidewalk Design. From 1924 to 1931, he was a member of the Boston Society of Civil Engineers, and, at one time, a member of the New England Water Works Association.

In 1895 Mr. Conant was married to Elfletah Launey, of Savannah, who survives him as do two daughters, Mrs. Edmund Francis Leland, Jr., and Mrs. Ralph S. Robinson, each of whom has three children. For several years prior to his death, Mr. Conant resided in Belmont, Mass., spending his winters in Florida.

His engineering work was constructive and sound and made its contribution to that reputation for reliability and integrity which is one of the chief assets of the profession. His activities brought him frequent notice in the local newspapers, and he received many expressions of commendation. At all times he had in mind the factor of cost and although receptive to new methods, he constantly aimed at efficiency and economy.

In temperament, Mr. Conant was fortunate, possessing an even and cheerful disposition. Courteous and kind to all, he was singularly free from petty animosities. He had a wide circle of friends, and he leaves a pleasant memory.

Mr. Conant was elected a Member of the American Society of Civil Engineers on March 13, 1917.

HUGH LINCOLN COOPER, M. Am. Soc. C. E.[1]

Died June 24, 1937

Hugh Lincoln Cooper was born in Sheldon, Houston County, Minn., on April 28, 1865, the elder son of George Washington and Nancy Marion (Parshall) Cooper, grandson of James Henry and Phoeba Lavinia (Bailey) Cooper, and great-grandson of James Henry Cooper, who came from England and settled in Montgomery County, Illinois. His early schooling was in Rushford, Minn., Grade and High Schools. At the age of seventeen, while working for a farmer, during a school vacation, he designed and built a timber highway bridge for his employer, across Money Creek which flowed through the farm. This bridge, with a span of 40 ft, and resting on stone piers, was in service for about forty years.

This early interest in engineering construction developed into a firm determination to become an engineer. In order to gain the necessary practical experience, Mr. Cooper had to leave home, after he was graduated from the Rushford High School in 1883, and seek employment in the field of his chosen profession. Employment of an engineering nature was not immediately available, however, and in order to support himself, he worked in a livery stable in Eau Claire, Wis., which was operated as a part of a piano firm for the delivery of pianos and organs. He soon became a Salesman for the firm, and successfully followed that calling until March, 1884, when he obtained employment with the Chicago, Milwaukee and St. Paul Railroad Company, as an Axman and Rodman in an engineering party assigned to a bridge-building project at Chippewa Falls, Wis. Mr. Cooper's intuitive engineering knowledge and ability enabled him to master the details of the bridge and its construction, so that when the Contractor failed and the Resident Engineer was unable to continue the work because of illness, he was given complete charge of the job and finished the bridge to the entire satisfaction of the Chief Engineer of the Railroad Company.

---

[1] Memoir prepared by Valentine Ketcham, Esq., of Stamford, Conn., and Brig.-Gen. M. C. Tyler, Corps of Engrs., U. S. Army, M. Am. Soc. C. E.

This accomplishment made him decide to specialize in bridge building, and, in January, 1885, he entered the employ of the late Horace E. Horton, M. Am. Soc. C. E., Bridge Engineer, with offices in Rochester, Minn. After an intensive apprenticeship of several years Mr. Cooper was made Superintendent of erection of the High Bridge and the Wabash Street Bridge across the Mississippi River, in St. Paul, Minn. Upon the completion of this work in 1889, he was transferred to Chicago, Ill., as Superintendent and Assistant Chief Engineer of Mr. Horton's Chicago Bridge and Iron Works, where he remained for two years.

In 1891, he became the Manager of a Branch Office of the San Francisco Bridge Company, in Spokane, Wash., and built several railroad and highway bridges in that territory, among them a steel cantilever bridge 500 ft long for the Spokane Falls and Northern Railway Company.

In 1894, Mr. Cooper became interested in hydro-electric engineering—then in its infancy—believing that it offered more opportunities and advantages than bridge building. He made an examination for a small water-power development on the Missouri River, at Canyon Ferry, Mont., for the late John T. Fanning, M. Am. Soc. C. E., Consulting Engineer, located the site, and put in the foundations. By this time he had fully decided to devote his entire energies to hydro-electric engineering, and, therefore, abandoned his bridge-building career.

Wishing to learn more about this new science, he applied for work, in 1896, with Stillwell, Bierce, Smith-Bailey Company, of Dayton, Ohio, which firm manufactured water-wheels and built small hydro-electric plants in which to install them. He was told there was no work for him, but he explained that he wanted to learn about water-wheels and would gladly work without pay. His perseverance won him recognition on these terms and he worked without compensation for several months. Eventually, he was made Assistant Chief Engineer of the Company and designed or built (or both) hydro-electric plants at Ellenville, and Dolgeville, N. Y., and on the Island of Jamaica, British West Indies.

In 1898, Mr. Cooper joined the organization of the late Fred Stark Pearson, M. Am. Soc. C. E., in New York, N. Y., and built two granite dams for the 20 000-hp high-head hydro-electric station of the São Paulo Tramway, Light and Power Company, Limited, on the Tieté River, in Parnahiba, Brazil.

He returned to the United States in 1901, and for a short time was associated with the firm of Viele, Blackwell, and Buck, in New York City. He located, designed, and, later, built a hydro-electric plant for the Winnipeg General Power Company on the Winnipeg River, near Winnipeg, Man., Canada.

In 1902 and 1903, as Chief Engineer of the Mexican Light and Power Company, of Montreal, Que., Canada, he was engaged in the design and location of a high-head hydro-electric plant in the mountains of Mexico, at Salto Grande, on the Necaxa and Tenanga Rivers, for the street railways of the City of Mexico, Mexico.

Simultaneously, he located, designed, and constructed the 100 000-hp plant for the Electrical Development Company of Ontario, Limited, at Niagara Falls, Ont., Canada, above the Horseshoe Falls. The design included two daring and unique features—first, a wing dam extending into the Niagara River a short distance above the Falls, where the water attained a velocity of more than 20 miles per hr; and, second, a tail-race tunnel discharging directly behind the waters of the Horseshoe Falls. Both these features seemed fantastical and impossible of accomplishment, when first proposed, but both were successfully completed and the plant was put in operation in 1907.

In 1905, Mr. Cooper opened his own office for private practice, in New York City. In 1906, 1907, and 1908, he designed and for the greater part built the hydro-electric plant for the Pennsylvania Water and Power Company on the Susquehanna River, at McCalls Ferry, Pa.

In 1907, he visited Japan as a Consulting Engineer on the Lake Biwa project in that country. During this same year, he started the designing and financing of the low-head hydro-electric plant on the Mississippi River, at Keokuk, Iowa, which was started in 1910 and completed in 1913.

In 1913, Mr. Cooper was invited by the Egyptian Government to make a survey of a proposed power plant, which would be a part of the Assuan Dam on the River Nile, and the output of which was to be used in the manufacture of fertilizer. Plans were prepared and accepted for a plant capable of generating 200 000 hp, but the outbreak of the World War in 1914 caused the abandonment of the project.

In 1914, he again opened offices in New York City, where he continued a general consulting engineering practice.

When the United States entered the World War in April, 1917, he volunteered to serve, and, in May, was appointed a Major of Engineers. He was ordered to France where he arrived in July. During the preliminary stages of the organization of the engineering activities of the Service of Supply of the American Expeditionary Forces, Major Cooper was engaged on the duty of making investigations and plans for the development and use of base-port facilities and as Consultant to the Chief Engineer of the Expeditionary Forces on many of the difficult construction problems that had to be solved. He was promoted to the rank of Lieutenant-Colonel in October, 1917. On the recommendation of the Chief of Engineers of the Army, Lt.-Col. Cooper was ordered back to the United States in March, 1918, to begin the construction of the navigation and hydro-electric power development at Muscle Shoals, Ala., which was intended to furnish energy to the War Department Atmospheric Nitrogen Fixation Plant then being built as a war measure for the production of explosives. In April, 1918, he was promoted to Colonel of Engineers. In May, 1918, at the request of the Commanding General, A. E. F., Colonel Cooper was relieved from duty at Muscle Shoals and again ordered to France where he served as Section Engineer of Base Section No. 2 at

Bordeaux, supervising the construction of camps, hospitals, docks, railroads, and other engineering works in that area. For this service he was awarded a Meritorious Citation Certificate by the Commanding General of the American Expeditionary Forces for "Exceptionally Meritorious and Conspicuous Services as Engineer Officer, Base Section No. 2, A. E. F." By the French Government, he was awarded the Order of the University of Palms, grade of Officier d'Instruction Publique.

After the war, Colonel Cooper held a commission as Colonel, Engineer Officers' Reserve Corps, until he reached the age of 64 when he was transferred to the Auxiliary Reserve.

In May, 1920, he entered into an agreement with the Chief of Engineers, U. S. Army, who had been ordered to proceed with the construction of the Wilson Dam, at Muscle Shoals, which provided that Hugh L. Cooper and Company would act as Consulting Engineers, in the design and construction of this project. Under this contract, Colonel Cooper furnished the Chief of Engineers with general and detailed plans of the main dam, the power house, its hydraulic and electrical machinery, and the lock system for navigation, together with complete specifications for all the work. He also passed upon the acceptability of all foundations, and inspected all permanent work through a Resident Engineer and a Corps of Inspectors, terminating his contract with the completion of the project in 1926.

Between November, 1919, and 1926, he made the following important engineering studies and reports relating to the United States-International Waterways situation:

First.—A general investigation for the Frontier Corporation of the power and navigation potentialities of the St. Lawrence River, particularly in its international section.

Second.—A comprehensive report to the Hydro-Electric Commission of Ontario on the general design and cost of its Chippewa Generating Station.

Third.—A report, at the request of Herbert Hoover, Hon. M. Am. Soc. C. E., then Secretary of Commerce in President Coolidge's Cabinet, on the St. Lawrence problem as a whole, including the results of intensive studies as to restoring and perpetuating the scenic beauty of the Horseshoe Falls in the Niagara River.

In 1926, Colonel Cooper was chosen by a Government Commission of the Soviet Republic to go to Russia to study and report upon a projected power plant below the Kitchkas Rapids, in the Dnieper River, in the Ukraine. In February, 1927, he entered into a contract with the Soviet Government to design and supervise the construction of this 800 000-hp project which included a series of locks and required an expenditure of more than $100 000 000. This work was carried through to a most satisfactory and successful conclusion, and when the project was formally accepted in August, 1932, by the Soviet Commissariat of Heavy Industry, Colonel Cooper was awarded the Order of the Red Banner by the Government of the Soviet Republic, the highest civil honor that can be awarded to any non-citizen.

In 1928, the Egyptian Government appointed him a member of an International Commission of three engineers to pass upon the feasibility of raising the Assuan Dam on the River Nile. The survey was made, plans and specifications were prepared to raise the dam 30 ft, and the work was carried to a successful completion, providing water for the cultivation of 700 000 additional acres of land in the Nile Valley.

Colonel Cooper's last active work was as a Consulting Engineer for the Union Carbon and Carbide Company, on a high-head hydro-development on the Kanawha River in West Virginia. At the time of his death, he was working on plans for a huge development in Z-Canyon, on the Columbia River, in Washington, the electrical development of the Nile at Assuan, which had been recently revived, and a hydro-electrical development in Greece.

He had been a resident of Stamford, Conn., since 1901. He had been prominent in its civic, and active in its religious, life; he attended the First Congregational Church. He belonged to the Hubbard Heights Golf Club and Woodway Country Club, in Stamford; the New York Yacht Club and the Uptown Club, in New York City; The Congressional Country Club, in Washington, D. C.; Royal Societies Club, London, England; Engineers Club, of St. Louis, Mo.; Engineers Club, of Kansas City, Mo.; and the Harrisburg Club, of Harrisburg, Pa.

The following honorary degrees had been conferred upon him: Doctor of Engineering, by the Polytechnic Institute of São Paulo, at São Paulo, Brazil; Doctor of Laws, by Parsons College, Fairfield, Iowa; Doctor of Laws, by the University of Missouri, at Columbia, Mo.; and Doctor of Engineering, by Syracuse University, at Syracuse, N. Y.; also a degree as Minister of Public Instruction of the Republic of France, and the Beaux Arts.

He was a member of the American Society of Mechanical Engineers, the American Institute of Mining and Metallurgical Engineers, American Institute of Consulting Engineers, the Society of American Military Engineers, also the Institution of Civil Engineers, and the Institution of Water Engineers, of Great Britain.

Colonel Cooper was intensely interested in government and economics and wrote several monographs relating to these subjects from the engineer's point of view.

He had a striking and unique personality. His intuitive technical knowledge and his broad engineering experience commanded the respect of all, but he was admired not only for his eminence in his chosen profession, but for what he was himself. He was absolutely candid in all personal relations, frank and sincere in his judgments, outspoken in the expression of his convictions, and absolutely honest in everything that he did. He inspired men with his vigor and enthusiasm and friendliness; every one loved him and considered it a privilege to be associated with him. He possessed a rare combination of good common sense and genial humor and radiated cheerfulness and vitality in every circle in which he moved. His friends were always glad to be with him and enjoyed the impact of his vigorous and rugged personality. The twinkle in his eye, the chuckle in his voice, his pithy and pointed comments on life, endeared him to all and made him delightful company. He will ever be remembered as a gentleman of distinction, a citizen of sterling worth, a patriot whose love of country was courageous and sincere, and an engineer pre-eminent.

He was married at Rochester, Minn., on October 12, 1892, to Frances B. Graves. He is survived by his widow and two daughters, Mrs. Ralph H. Sheldon and Mrs. John R. Hardin, Jr., and a sister. A brother, Dexter Parshall Cooper, M. Am. Soc. C. E., died on February 2, 1938.

Colonel Cooper was elected a Member of the American Society of Civil Engineers on September 6, 1905.

ERLE LONG COPE, M. Am. Soc. C. E.[1]

Died March 19, 1937

Erle Long Cope was born on March 25, 1883, at Meridian, Calif., the son of Leroy Cope and Ida (Long) Cope. His father was for many years a much respected county official of Sutter County, California, where Erle's boyhood was spent. He was graduated from the High School, at Marysville, Calif., in 1902. Four years later he was graduated from the College of Civil Engineering of the University of California, at Berkeley, Calif.

During his college vacations Mr. Cope readily found employment with the County Surveyor of his home county. Immediately after his graduation he spent a short period with the Engineering Staff of the Southern Pacific Company, at Los Angeles, Calif., and then returned to San Francisco, Calif., where he was employed by the firm of Couchot and O'Shaughnessy, first in designing the structural features of buildings under the direction of the late M. C. Couchot, M. Am. Soc. C. E., and, thereafter, as Resident Engineer of the Dulzura Conduit of the Southern California Mountain Water Company in San Diego County, California, under the immediate direction of the late M. M. O'Shaughnessy, M. Am. Soc. C. E.

After the completion of this assignment Mr. Cope did some important structural designing for the firm of Couchot and Thurston (E. T. Thurston, M. Am. Soc. C. E.). In April, 1909, he became an Assistant Engineer with John Galen Howard, Architect, in which capacity he had opportunities to exercise his great ability in solving difficult problems of structural design. He also supervised the construction of some of the important buildings of the University of California. Thereafter, he did some work on water-power projects and valuations.

From September, 1912, until August, 1934, Mr. Cope maintained an office in San Francisco, part of the time with associates and part of the time in independent practice, specializing in Structural Engineering. During this period he carried on such varied work as the purchase of equipment, machinery, and materials for bridges and structures in the Dutch East Indies; the investigation of irrigation projects in California; the design of a number of pump houses for the Banta-Carbona Irrigation District; and the structural engineering of several buildings in San Francisco and neighboring cities, including the Mills Tower, the Stock Exchange Building, the Apparel Center Building, and others. He also designed and superintended the construction of bridges and concrete viaducts in Sutter County and many other smaller structures.

---

[1] Memoir prepared by Walter L. Huber, and Thomas H. Means, Members, Am. Soc. C. E.

He was in charge of the Bureau of Building Inspection of the City of San Francisco from August, 1934, until his untimely death on March 19, 1937. His administration of this Bureau was characterized by impartiality and fairness and, as in other employment, he made no effort to spare himself. He was a prodigious worker. His direct and frank manner won for him many friends.

He is survived by his widow, Mrs. Gladys W. Cope, his mother, Mrs. Ida Cope, and a brother, Jesse.

He was a member (Director, 1932–33, and President, 1933) of the Structural Engineers Association of Northern California. He was also a member and President (1933) of the Structural Engineers Association of California, and a member of the Engineers' Club of San Francisco.

Mr. Cope was elected a Junior of the American Society of Civil Engineers on January 7, 1908; an Associate Member on December 6, 1910; and a Member on November 27, 1917. He was, throughout his membership, active in the San Francisco Section, and, at various times, was a member of a number of the Section's Committees.

THURSTON CARLYLE CULYER, M. Am. Soc. C. E.[1]

DIED DECEMBER 9, 1936

It is difficult to express in cold type the work and achievements of one who is gone, and to put the warmth of life into the memoir of a friend, making it alive to the associates who survive. The writers, who were friends of Mr. Culyer for more than fifty years, realize this, but they wish to pay a tribute of respect to the fine traits of his character, to his high sense of honor, and to the loyalty he showed to his work and to his friends. They know that he put into his work the best that was in him and they wish his devotion to it was better known.

Thurston Carlyle Culyer was born in the Washington Square section of New York, N. Y., on September 19, 1864, the son of John Y. and Phœbe A. (Matthias) Culyer. His paternal ancestry extended back to Thomas and Elizabeth Norton, of Norfolk, England. John Culyer, the grandson of Thomas Norton, came to the United States about 1829 and settled in New

---

[1] Memoir prepared by Edward S. Larned, Esq., Boston, Mass., and Robert Ridgway, Past-President and Hon. M. Am. Soc. C. E.

York City. His son—John Y. Culyer, the father of Thurston Carlyle Culyer—was a noted Landscape Architect and Engineer who served as an Assistant Engineer on the construction of Central Park, New York City, until the Civil War. He then became Assistant Secretary of the United States Sanitary Commission, and, later, joined the Engineering Branch of the Federal Military Forces and served in the defenses south of the Potomac River under the late Major-General John Gross Barnard, U. S. A., Hon. M. Am. Soc. C. E. After the war, John Y. Culyer was again employed as an Engineer in Central Park until 1872 when he became an Assistant Engineer, and, later, Chief Engineer and Superintendent, of Prospect Park, in Brooklyn, N. Y., and other parks in that city, remaining in this service until 1886. Subsequently, he was engaged in general and consulting practice as a Landscape Architect and Engineer, in which field he gained a wide and enviable reputation. For twenty-five years John Y. Culyer served as a member of the Board of Education of Brooklyn, and was active in the New York State National Guard, attaining the rank of Lieutenant Colonel. His son—Thurston—inherited his love of trees and of nature generally.

Thurston Carlyle Culyer obtained his preliminary education in the Friends Seminary, in Brooklyn, and then spent four years (1878 to 1882) at the Brooklyn Collegiate and Polytechnic Institute, later, the Polytechnic Institute of Brooklyn. Between September, 1882, and January, 1883, he was with the Drainage Construction Company, of Boston, Mass., on the building of 13 miles of sewer in Keene, N. H. On July 1, 1884, he was appointed a Chainman in the service of the Department of Public Works of New York City, under the late George W. Birdsall, Chief Engineer, and worked in the Croton water-shed on surveys for the new Croton Aqueduct and the Muscoot Dam. Later, Mr. Culyer was promoted, successively, to the positions of Rodman, Leveler, and Transitman with increasing responsibilities, and on September 20, 1892, to the position of Assistant Engineer in charge of all work for the Department in the Croton water-shed in Westchester and Putnam Counties.

When, in 1898, the several outlying Boroughs were consolidated into the Greater City of New York, the City departments were re-organized and the functions of the Department of Public Works were merged with those of the new Department of Water Supply, Gas, and Electricity, Mr. Culyer continued with the new Department's Bureau of Water Supply, his work including the design and construction of sanitary structures for the protection of the water supply. From March, 1910, until his retirement, he was in charge of all the reservoirs and aqueducts of the Croton and Bronx River Systems, including the reservoirs within the City limits—such as Jerome Park, High Bridge, and Central Park. In 1914, there was added to his duties for a time the operation and maintenance of that part of the new Catskill Aqueduct which extended from the Hudson River crossing at Storm King to the City line.

Some of his associates feel that Mr. Culyer's most important contribution to the service was his sanitation work which began in 1892 during a scourge of cholera in New York City. Previous to that time land acquisition in the water-shed was confined largely to the actual needs of the reservoirs built and the consequent road substitutions. Mr. Culyer's opinion had great weight in deciding the authorities to acquire about 3 000 acres for the sanitary protection of the streams and for the actual removal of the then existing gross sources of pollution. He was also instrumental in abating many minor sources of pollution existing elsewhere in the water-shed.

In 1893, he constructed a plant for the disposal of sewage of a part of the Village of Brewster, N. Y., which was unique in that it provided for the sterilization of sewage by electrically dissociating common salt as a source of chlorine. His interest in sterilization continued, and shortly after the experiments made by the late George A. Johnson, M. Am. Soc. C. E., at the Chicago (Ill.) stockyards, Mr. Culyer began the sterilization, with bleach powder, of the flow of the new Croton Aqueduct—probably the first large city in the United States to furnish this safeguard. Later, on the line of the aqueduct at Dunwoodie, N. Y., he built a sterilization plant designed to use this material accurately and, later, as knowledge of liquid chlorine became available, converted the Dunwoodie plant to its use. He was also responsible for the setting out of the large plantings of evergreen trees on the marginal lands about the reservoirs in the Croton water-shed, that does so much to enhance their beauty and attractiveness. His taste for such work was remarkable. He knew every phase of the work under his charge, and loved it and the beautiful country in which it was located.

On January 1, 1919, Mr. Culyer was retired from the service of the City which he had served so faithfully and well for thirty-five years—nearly all his working life. One of his associates in the Department writes:

> "His love for the trees, the flowers and streams made him one of those whose life work on the watershed was more a pleasure than a task, and in his contact with the countryside he was more the squire than the stern representative of the big city whose water supply he so carefully guarded. In his retirement, New York City lost a loyal and competent engineer who devoted himself to her interests to the exclusion of all others."

After his retirement, he became identified with the real estate firm of Pease and Elliman, of New York, as a Real Estate Appraiser, and served with this firm until a short time before his death. For a number of years he was afflicted with a serious heart trouble which was a source of constant concern to his friends and his devoted wife. He died of a sudden attack on the night of December 9, 1936.

Mr. Culyer was respected by, and possessed the sincere affection of, those who were privileged to know and be associated with him. That he was not better known to the Engineering Profession and to the community was due to his modesty and a disinclination to put himself forward. He had a high sense of honor and left behind a record of which his friends are proud.

He had vision and a good sense of humor. He possessed a rare ability for sketching. He was a Charter Member of the Municipal Engineers of the City of New York, and a member of the American Water Works Association.

He was married, on February 6, 1892, to Edith Mead Stocum, of Purdys, N. Y., who, with a daughter, Katharine Grey Culyer, and a sister, Marian Prescott Culyer, of Mount Kisco, N. Y., survives him.

Mr. Culyer was elected a Member of the American Society of Civil Engineers on June 4, 1913.

WILLIAM HERBERT CUSHMAN, M. Am. Soc. C. E.[1]

Died October 10, 1937

Members of the Society and his many other friends were greatly shocked by the accidental death, in an automobile accident, of William Herbert Cushman, Engineer of the Works Progress Administration, which occurred near Watertown, N. Y., on October 10, 1937.

William Herbert Cushman was born at Duxbury, Mass., on March 27, 1869, a son of Alden and Jane (Hatch) Cushman. He was a descendant of Robert Cushman, one of the founders of Plymouth Colony, in Massachusetts.

After High School, he attended a private academy, and, from 1887 to 1892, worked with E. W. Bowditch, a Civil Engineer, of Boston, Mass., on topographic surveys, sewer surveys, estimates, and construction. In 1892, Mr. Cushman was engaged by the Town of Lancaster, N. H., to supervise the construction of a water supply system; in 1893, he had charge of a water supply system at Sistersville, W. Va.; and from January to September, 1894, was associated with Hoge and White, City Engineers of Wheeling, W. Va. From February, 1895, to September, 1896, he was District Superintendent, Street Cleaning Department, of New York, N. Y., under Col. George E. Waring, Jr. During this time, he collected data and submitted a report leading up to the construction of the Barren Island Reduction Plant.

For five years, 1897 to 1902, Mr. Cushman was Resident Engineer in charge of construction of the 52 000-hp hydro-electric project on the St. Lawrence River, at Massena, N. Y., which was built by the St. Lawrence Power Company. The late John Bogart, M. Am. Soc. C. E., was Engineer-in-Chief, and Kincaid, Waller, and Manville, of London, England, were Associated Engineers on this project. The plant is now owned by the Aluminum Company of America.

In May, 1902, the principal construction work for the Massena development having been completed, Mr. Cushman continued his association with Colonel Bogart by making preliminary studies and design for a 12 000-hp hydro-electric development on the Chattahoochee River at Morgan Falls, about twenty miles north of Atlanta, Ga., on which Colonel Bogart was then Consultant. Mr. Cushman prepared the design and in August went to Morgan Falls and started the construction, remaining on the site until all but minor details were completed. This job was especially appealing to his energetic nature as the urgent desire to place the plant in operation permitted an unusual amount of authority over the contractor's operations being placed with the engineer. The construction was completed in 1904.

---

[1] Memoir prepared by William T. Field, and Charles A. Pohl, Members, Am. Soc. C. E.

From August, 1904, to August, 1905, he was Resident Engineer on the Oswego Division of the New York State Barge Canal. As such, he had charge of all field work and studies connected with the contracts for two locks and the canal through the City of Fulton, N. Y., and had completed much of the field and design work for the remainder of the canal, along the Oswego River, when he left the State employ.

From August, 1905, to January, 1907, Mr. Cushman was Chief Engineer of a hydro-electric development on the Juniata River, near Huntingdon, Pa., for the Juniata Hydro-Electric Company. This project had a 6 000-hp hydro-electric plant and a 3 000-hp steam auxiliary which furnished light and power to Altoona, Pa., and neighboring towns.

In 1907, he was Engineer and Superintendent for W. J. Oliver and Company, Contractors for the Hales Bar Dam, across the Tennessee River, near Chattanooga.

In 1908, Mr. Cushman was Resident Engineer, representing Sellers and Rippey, Consulting Engineers, of Philadelphia, Pa., on a hydro-electric development on the Estacada River, about 25 miles southeast of Portland, Ore., for the Portland Railway, Light, and Power Company. Great difficulties from leaks, due to a porous foundation, were encountered on this work.[2]

From 1910 to 1913, he was engaged in private practice as a Consulting Engineer, making investigations, reports, and giving expert testimony on hydraulic power work. In 1913, he served as Engineer and Superintendent for James Stewart and Company, on the construction of the Barge Canal, at Scotia, N. Y., involving caisson work, and, in 1914 and 1915, he designed and built a hydraulic power plant on the Genesee River, at Mt. Morris, N. Y.

As head of the Hydraulic Construction Company, Mr. Cushman built a dam and reservoir for the City of Johnstown, N. Y., at Rockwood, N. Y. During the World War, this Company built a steam-electric plant for the New York Air-Brake Company, at Watertown, which Company was engaged in making munitions for the Federal Government. Several other buildings and structures were built by the Hydraulic Construction Company, during the period, 1915 to 1920.

From 1917, for a considerable period, Mr. Cushman was also associated with the firm of Jones and Hazel, at Watertown, in the investigation and appraisal of water-power projects and, in this connection, he appraised more than 150 hydraulic power installations. He was also retained during this time by the Federal Treasury Department to study and criticize reports pertaining to water-power development from all parts of the United States, and appeared many times as an expert witness in legal proceedings pertaining to water power.

In 1920, Mr. Cushman opened an office as a Consulting Engineer, in Watertown. He designed and supervised the construction of a 7 500-hp hydro-electric development for the St. Regis Paper Company, at Black River,

---

[2] *Transactions*, Am. Soc. C. E., Vol. LXXVIII (1915), p. 447.

N. Y., and, from 1921 to 1924, was Consultant for the City of Watertown in the development of a 7 500-hp hydro-electric plant for that city.

In 1926 and 1927, he designed and supervised the construction of a 2 200-hp hydro-electric development for the Newton Falls Paper Company, at Newton Falls, N. Y.

When the Temporary Emergency Relief Administration was organized in 1934, Mr. Cushman was named Project Engineer and, later, County Engineer, under the Works Progress Administration, at Watertown.

He was essentially a positive individual. He was a dynamo of energy, always active. He always used direct methods of approach which might have been construed as lacking in tact. On account of his sincere directness and abhorrence of evasion or equivocation, he knew no other way. He sometimes was impatient over restraint, especially when he thought that it might properly have been avoided. He was as stalwart in character and physique as Plymouth Rock in the shadow of which he was reared.

As an engineer, Mr. Cushman was particularly gifted with common sense—not only in directing men, but in handling the forces of Nature as found in his chosen field of damming and controlling rivers.

He was a loyal friend, but he never allowed friendship to interfere with the administering of discipline if needed or in the best interest of any work under his charge. Many have said of him, "No man could deny his word, integrity, or ability."

On April 19, 1891, he was married to Ida M. Wanamaker, and there were two children, Eugene A. Cushman, who died in Texas, and Dorothy E. (Cushman) Littlewood, who, with Mrs. Cushman, survives him.

He was a member of the New York State Society of Professional Engineers, and of the Benevolent and Protective Order of Elks.

Mr. Cushman was elected a Member of the American Society of Civil Engineers on January 3, 1906.

HARRY JOCELYN DIGNUM, M. Am. Soc. C. E.[1]

DIED DECEMBER 26, 1936

Harry Jocelyn Dignum, who was born on June 26, 1878, in Falmouth, Jamaica, British West Indies, was one of the pioneer engineers who risked their lives in the early days of construction on the Panama Canal when American engineers began to change the Isthmus from a pest hole of disease to a place of comfortable homes and modern methods of living.

His birthplace, the seaport of Falmouth in the Parish of Trelawny, was one of the oldest sugar-producing areas in the West Indies. His father, Judge Andrew B. Dignum, Resident Magistrate of Trelawny, was an ardent sportsman, and the owner of a fine racing stable. It is not strange, therefore, that Harry Jocelyn Dignum was known for his love of fishing, shooting, riding, and polo, as well as for his strength of character, engineering ability, and as an authority on sugar production.

---

[1] Memoir prepared by Norman J. Dignum, Esq., Miami, Fla.

In 1899, he was graduated from Jamaica College, and went to work for the Jamaican Government Railroad Company, building concrete tunnels, keeping costs, etc. After two years in this work he left the Island of Jamaica for Ecuador to take a position as Junior Engineer on the Guayaquil to Quito Railroad. After having risen to be Engineer in Charge of Camp and Construction on this railroad, Mr. Dignum returned to Jamaica with blackwater fever. Three of his senior engineers and sixty of the one hundred imported laborers had succumbed to the ravages of malarial and yellow fevers.

The following year, fully recovered from his illness, he returned to the service of the Jamaican Government Railroad Company as Engineer in Charge of Terminal Buildings and Construction. In 1905, he again left Jamaica, this time to work for the Isthmian Canal Commission as Instrumentman and Transitman, and, later, as Engineer in charge of surveys and sewer construction, dams, and water supplies. He returned to the Jamaican Government Railroad Company in 1908 as Superintendent of Construction and Maintenance of Railroad Tracks and Buildings.

In 1909, Mr. Dignum was appointed by the Government as Superintendent for Messrs. Nicholson and Corlette in charge of construction of Government buildings.

The following year, 1910, he again left Jamaica to go to Cuba where he was employed as Superintendent of Construction and Engineer of Surveys for Water Supplies by the United Fruit Company, in Preston. From 1914 to 1915 he was Resident Engineer of the Cuba Railroad Company and the Guantanamo Sugar Company on railroad location and construction.

Back with the United Fruit Company in 1916, he spent two years in Tela, Spanish Honduras, as Engineer in charge of bridge construction and Superintendent of general construction. Still with the United Fruit Company, he was transferred to Jamaica to take charge of topographical surveys. For the four years between 1918 and 1922 Mr. Dignum was General Superintendent of the Baragua Sugar Company in charge of railroad surveys and construction, general construction, and the design and construction of wharves and lighters. He also charted and supervised the dredging of ship channels, and was in charge of the transportation of sugar and cane.

From 1933 to 1935, Mr. Dignum was employed by the National City Bank of New York, N. Y., and the Royal Bank of Canada, as Assistant Manager in the readjustment and operation of their sugar mills in Cuba. In 1935, he was attached to the British Legation in Havana, Cuba, as Inspector of Immigration for the Jamaican Government.

He served as Assistant Manager of the Cayo Mambi Sugar Mill for the Atlantic Fruit Company from 1926 to 1930. In 1931 when the business depression forced many sugar companies into bankruptcy, Mr. Dignum returned to Jamaica where he was employed as Surveyor in the Surveyor General's Office, in Kingston, until illness forced his retirement in 1936.

Years of exposure, tropical fevers, and self-sacrificing work finally broke down an iron constitution, and deprived him of his cherished dream—a modern sugar mill on the River Martha Brae in his beloved Trelawny. On December 26, 1936, at the age of 58, a Master Mason, with thirty-eight years of experience in every line of civil engineering and at the peak of his capabilities, he died at his home in the suburb of Kingston, Jamaica. He is survived by his widow, Helen A. Dignum, two sons, Norman J. and Harry, and one daughter, Daphne.

Mr. Dignum was elected an Associate Member of the American Society of Civil Engineers on April 2, 1913, and a Member on April 4, 1922.

JOSEPH OSCAR ECKERSLEY, M. Am. Soc. C. E.[1]

DIED NOVEMBER 19, 1930

Joseph Oscar Eckersley was born on September 12, 1873, in New York, N. Y. He received his preliminary education in the New York public schools, attended Columbia University from 1895 to 1897, and was graduated in 1899 from Cooper Union Institute, with the degree of Bachelor of Science. He continued his studies there for two years (1906–1908), and also acted as Night School Instructor in Mechanical and Structural Drawing and Machine Design, receiving his Civil Engineering degree in 1908.

Before his college days were over Mr. Eckersley had obtained some practical engineering experience. He had been employed from 1894 to 1895 as Rodman and Transitman in charge of municipal work for the City Engineer of Mount Vernon, N. Y.; as Transitman with J. A. Doolittle, Landscape Engineer, in charge of the design and layout of a masonry wall at Woodlawn Cemetery, New York City, from 1897 to 1899; as Engineer with Terry and Tench Construction Company, New York City, checking erection sheets for the Boston (Mass.) Elevated Railroad, the New York Rapid Transit Subway, a ten-story steel-frame building, and designing derricks, falseworks, etc., for the erection of structures. In 1900 he served in the Topographical Bureau in the Borough of The Bronx, New York City.

After qualifying in a civil service examination as a bridge draftsman, Mr. Eckersley was appointed in 1901, by the Department of Bridges (later, the Department of Plant and Structures), for the City of New York; and, in 1902, he became Assistant Engineer. The next year he served as Assistant Engineer on design and details of Blackwell's Island Cantilever (later, the Queensborough) Bridge, and on calculations and design for an eye-bar top chord in place of the existing cable for the Manhattan Bridge—both over the East River.

---

[1] Memoir prepared by W. R. Bascome, M. Am. Soc. C. E., and Theodore Belzner, Affiliate, Am. Soc. C. E.

Mr. Eckersley was Resident Engineer-in-Charge of the construction of the University Heights Bridge over the Harlem River, including caisson and coffer-dam work, sewers, dock work, etc., the cost of which amounted to approximately $900 000. This bridge was completed in 1908.

As Assistant Engineer, Mr. Eckersley also had responsible charge of reviewing the design and check calculations for different types of loading for Blackwell's Island Bridge, and adjustments of the structure prepared by the late William H. Burr, Hon. M. Am. Soc. C. E., and the late Alfred P. Boller and H. W. Hodges, Members, Am. Soc. C. E., Consulting Engineers. In 1916, he made preliminary studies of layout and design for the Tri-Borough Bridge, connecting the Boroughs of Manhattan, The Bronx, and Queens, and studies for the Hendrick Hudson Memorial Bridge over the Harlem Ship Canal.

In January, 1916, Mr. Eckersley was appointed Engineer-in-Charge of the Division of Design, and supervised the design of the Eastchester Bridge, over Eastchester Creek, in The Bronx, a double-leaf bascule bridge with a span of 127 ft 8 in., and the Beach Channel and North Channel Bridges, on the line of Cross Bay Boulevard, Jamaica Bay, Queens. The latter are double-leaf bascule bridges with a span of 123 ft. He was also in charge of the design for the Unionport Bridge, over Westchester Creek, in The Bronx, a double-leaf bascule with a span of 75 ft, and the Roosevelt Avenue Bridge, over the Flushing River—one of the largest lift bridges in the United States—which is a double-leaf bascule bridge with a span of 212 ft. The Roosevelt Avenue Bridge has one roadway and two footwalks on the lower deck, and three tracks for rapid transit railway trains on the upper deck.

Mr. Eckersley was also in charge of the Division of Design when plans and specifications were prepared for ten housing stations or garages in the various Boroughs, for the Department of Sanitation, New York City, two destructor plants or incinerators, and the Central Motor Repair Shop, in New York City.

From August, 1924, to January, 1927, he was associated with the Department of Public Markets, in New York City, as Chief Engineer of the design, preparation of plans, specifications, and construction of The Bronx Terminal Market, and the designs for markets in Manhattan and Brooklyn.

In January, 1927, Mr. Eckersley returned to the Department of Plant and Structures where he remained until his death on November 19, 1930.

He is survived by his widow, Mrs. Mary (Connolly), Eckersley, and a son, Joseph O. Eckersley, Jr.

As a specialist in bridge engineering, his most important accomplishments were in the designs and calculations for the great East River Bridges.

Mr. Eckersley was a lover of music and frequently attended the opera. He had many friends, and all who knew him were proud of this acquaintance. He was a member of the American Mathematical Society, and the Masonic Fraternity.

An intimate view of his character and outstanding qualities as an engineer is expressed briefly in the following tribute made by the members of Mr. Eckersley's staff, and his many engineering associates and friends:

"Mr. Eckersley affectionately known as 'J. O. E.,' was a deep and penetrating thinker. He read mathematics in many languages.

"As a professional man he was active in the interchange of technical information and opinion and in the maintenance of his professional and ethical standards.

"As a man, he was wise, honest and conscientious, considerate of the interests and opinions of his fellow men, a devoted husband and father.

"He was a man of sterling character. His exceptional ability, and judgment, and spirit of fairness in dealing with those with whom he came in close contact, won their admiration and respect. Although mild in manner, he was firm in his decisions and insistent in carrying out work according to the best practice. His clear-sighted analysis of conditions enabled him to arrive quickly at the proper solution of a problem and to point out the fault or error in a proper design."

"Mr. Eckersley was possessed of a keen scientific mind, and a thorough knowledge of mathematics and mechanics, he was always interested in developing a theoretical perfect structure.

"His untimely demise has removed an Engineer who was devoted to his profession and whose genial nature has won him a host of friends, both professionally and socially.

"His professional work was marked by a high degree of integrity. His death is deeply deplored by all his associates by whom he was held in the highest esteem and who hold his memory in affectionate regard."

A tribute to Mr. Eckersley was made by Leon S. Moisseiff, M. Am. Soc. C. E., as follows:

"I have known Mr. Eckersley from the time he came into the Department. He worked in my division a long time and I had a great liking for him and considered him one of my friends.

"* * * he was much interested in mathematics and had acquired a large library in that line especially in its more abstract branches. He was a profound student of mathematics and also showed much interest in philosophy, related as these subjects are. He was a thorough engineer.

"As a man he was very loyal and dependable. He had a high sense of justice and always endeavored to follow his views in life.

"He was one of the few men who leave in the minds of the people associated with him an indelible impression of personality and character. His memory is dear to me."

D. B. Steinman, M. Am. Soc. C. E., writes:

"I have always held Mr. Eckersley in the very highest regard for his character, interests and professional ability."

Mr. Eckersley was elected a Member of the American Society of Civil Engineers on August 31, 1909.

ALFRED DOUGLAS FLINN, M. Am. Soc. C. E.[1]

Died March 14, 1937

The death on March 14, 1937, of Alfred D. Flinn, Director, Engineering Foundation, brought to an end a career of exceptional engineering accomplishment encompassing in the first half of his life water supply development and technical journalism and in the latter half administration of the properties and the research activities of the four National Engineering Societies.

---

[1] Memoir prepared by Clinton L. Bogert, J. Vipond Davies, and Otis E. Hovey, Members, Am. Soc. C. E.

Alfred Douglas Flinn was the eldest child of Matthew Bonner and Sarah Jane (Jones) Flinn. He was born in New Berlin, Union Co., Pa., on August 4, 1869, in the old pre-Revolutionary homestead. His father was a practicing physician. He came of Irish-Scottish Presbyterian stock on his father's side, and among his ancestors on his mother's side were the early settlers of Connecticut. He was the eldest of six children of a busy country doctor who was often away from home over the country side on sick calls; during these absences, as recalled by his brother, Professor Frederick B. Flinn, Alfred D. Flinn "was a great comfort to his mother" and helped her to take care of the younger children. This willingness to lighten the responsibilities of others was one of Dr. Flinn's outstanding traits.

Another outstanding trait was his seriousness of mind, colored, however, with a prompt appreciation of humor. He only read the more serious books, and very rarely if ever attended the theatre. He was reading Shakespeare assiduously before he was eleven years old. At about this time in his boyhood, his next younger brother, to whom he was very much attached, died from injuries inflicted by another boy. After the brother's death, Alfred assumed a very serious and grown-up attitude toward life. His brother believes that this incident had a great deal to do with this attitude, and his lack of appreciation of the frivolities of life. His guiding motive was to improve himself and those around him.

Mr. Flinn started his schooling in Reedsville, Pa., but was graduated from the Providence, R. I., High School, whither his family had later moved. After graduating from High School, he went for a short period with the Boston and Albany Railroad Company in the Clerical Department, changing later to employment in the largest hardware company in Worcester, Mass. He remained in this work until 1889 when at twenty years of age, he was offered a junior partnership in the Company. This brought him to a crisis in his life, and he made the important choice of a career. He rejected a future career in the hardware business, for one in engineering.

He entered the Worcester Polytechnic Institute in the fall of 1889 and was graduated in 1893, with the degree of Bachelor of Science, in Civil Engineering, at which time he received the Salisbury Prize for high quality of work. His graduating thesis, "The Cippoletti Trapezoidal Weir," was based on large-scale experiments at the Holyoke Testing Flume. It was published[2] as a paper by the Society in 1894, and has been helpful in promoting the use of this means for measuring irrigation water in the United States.

After starting to work in Boston, Mass., Mr. Flinn took post-graduate evening courses at the Massachusetts Institute of Technology, and undertook home study, in mathematics, bridge design, and in other engineering subjects, and in science and literature. The notes which he made at this time were models of clarity and completeness. During the summer vacations, he was not idle, but found employment in engineering work with the City Engineer of Providence, R. I.

---

[2] *Transactions*, Am. Soc. C. E., Vol. XXXII (1894), p. 9.

Upon graduation from college, Mr. Flinn's first employment was with the firm of Rice and Evans, Civil Engineers, of Boston, of which the late George S. Rice, M. Am. Soc. C. E., of New York Subway fame, was head. With this firm he worked for several months on early studies for rapid transit in Boston, embracing the so-called "Alley Route"; he also was engaged on surveys for a proposed large public park.

The period from the fall of 1893 to the end of 1917—more than 24 years —was devoted mostly to specialization in water supply engineering, with the exception of a 2-yr interlude for editorial work.

During the winter and spring of 1893–94, Mr. Flinn was with the Associated Factory Mutual Fire Insurance Companies, of Boston, on experimental work on sprinklers and the flow of water in pipes; and on factory surveys for fire prevention. He then went to the Boston City Engineer's Office, in the Waterworks Division, on experimental work on all forms of fire-fighting apparatus used by the City of Boston, also, on pumping engines and boilers, and the flow of water in large pipes. He also made studies for the design of cast-iron pipes, special castings, and valves, and routine surveys for field work on the construction of pipe lines, reservoirs, and pumping stations.

On the formation of the Massachusetts Metropolitan Water Works in 1895, Mr. Flinn became Section Engineer on surveys, construction, and studies within the Metropolitan Area, under the late Frederic P. Stearns, Past-President Am. Soc. C. E., as Chief Engineer. Later, he became Principal Assistant Engineer in charge of the preparation of designs and contracts, the writing of reports, and various investigations, including experimental studies of dams, and the effects of ice on dams and other structures. These works comprised the Wachusett and Sudbury Systems of additional supply for more than twenty communities, and included large dams, reservoirs, aqueducts, pipe lines, stand-pipes, and pumping stations. The most notable structures were the Wachusett Dam and Aqueduct, the Weston Aqueduct, the Sudbury Aqueduct, and the Chestnut Hill Pumping Station.

In October, 1902, Mr. Flinn moved from Boston to New York City, in the vicinity of which (and chiefly in Westchester County), he made his future home. From October, 1902 to August, 1904, he was Managing Editor of *Engineering Record,* giving special attention to water supply and municipal engineering.

For the next year (to August, 1905) he was with the Croton Aqueduct Commissioners as General Inspector, which was a meaningless civil service name for responsible charge of the New York Office. Under the late J. Waldo Smith, Hon. M. Am. Soc. C. E., as Chief Engineer, Mr. Flinn was engaged on the designs, specifications, and contracts for the completion of the New Croton Dam and Reservoir, the Muscoot Dam and Reservoir, the one basin of the Jerome Park Reservoir, and the Jerome Park Pumping Station.

He was also in charge of studies of rainfall and stream flow of the Croton water-shed and of possible reservoir sites, to the end of providing quickly additional water to meet the City's needs until a new source could be developed. This work included the preparation of designs, contracts, and estimates of cost for the Cross River and the Croton Falls Dams and Reservoirs. These works cost several million dollars.

In August, 1905, when Mr. Smith was called from the Aqueduct Commission to become Chief Engineer of the Board of Water Supply of New York City, he showed his appreciation of Mr. Flinn's peculiar talents for organization by taking him with him, and making him in 13 yr, successively, Division Engineer (8 months); Department Engineer of the all-important Headquarters Department (9 yr); and Deputy Chief Engineer for 3½ yr. During this time, on Mr. Smith's absence from the City, Mr. Flinn acted as Chief Engineer. The work of the Board during the years of Mr. Flinn's connection with it covered construction totaling $140 000 000, and included the building of the Catskill Aqueduct, 90 miles long, the Ashokan and Kensico Dams, and two minor dams and four reservoirs, and studies for the Schoharie diversion. During this period, the combined forces of the Board and all contractors engaged on the Catskill Aqueduct reached a peak of 25 000.

Mr. Flinn's first responsibility was to recruit the Engineering Force of several hundred men under civil service restrictions and delays; he personally interviewed a large proportion of the engineers after they had passed the civil service tests. As Department Engineer, he was instrumental in outlining surveys and field studies; he was responsible for the designs for practically all structures and equipment; for the preparation of contracts and specifications; for estimates of cost; for the writing of special and annual reports; for inspection of manufactured materials; for the selection of consulting architects and co-operation with them; for co-operation with general and special consulting engineers, geologists, landscape engineers, sanitation specialists, and, during the World War, with the military organizations guarding the water-works; for the establishment and management of a special laboratory for research and the testing of materials, and for co-operation with other organizations in special researches and tests relating to steels, brasses, cements, and other supplies; for the preliminary studies, experimental tests, and final design of the aerators for the entire flow in the Catskill Aqueduct; for water-softening plants, filtration plants, small sewage disposal works; and, lastly, for City Tunnel No. 1 and the connecting pipe lines.

Mr. Flinn was called on to recommend to Mr. Smith, and to the late John R. Freeman Past-President, and Hon. M. Am. Soc. C. E., F. P. Stearns, Past-President, Am. Soc. C. E., and W. H. Burr, M. Am. Soc. C. E., his superiors, important changes in the materials of water-works construction. Until 1905, metropolitan water systems had used massive masonry constructions, grade tunnels (the exception being the pressure tunnel of the New Croton Aqueduct under the Harlem River), brick lining for tunnels, and cast-iron pipe siphons. As a result of Mr. Flinn's recommendations the Board of Water Supply used rubble concrete and ashlar stone facing for the dams; pressure tunnels to a greater extent than had been used heretofore in New York; concrete lining for all tunnels; aqueducts of concrete without brick lining; steel pipe siphons with concrete linings and jackets; reinforced concrete siphons; removable reinforced concrete beams and slabs in gate-chambers; reinforced concrete tile for chamber roofs; architecturally attractive superstructures; and landscaping and sodding for the tunnel spoil banks. It was due largely to his sense of fitness that Kensico Dam received such notable architectural treatment, and that the grounds below the dam were so strikingly landscaped.

Mr. Flinn undertook special investigations of the causes of defects in concretes in several locations and of "season cracking" of brasses; supervised the studies of an improved flexible joint for large submerged pipe lines; of special devices for closing the access and unwatering shafts of the pressure tunnels, including a novel scheme for unwatering; of grouting of rock tunnels; of unusual methods of core drilling for exploration purposes; of methods of construction and materials for large earth dams; and of drainage galleries and other special features of masonry dams.

His duties included also a wide variety of administrative activities and contacts with public officials. He delivered the illustrated address descriptive of the Catskill Aqueduct, the reservoirs, and structures, as part of the ceremonies by the New York City Government at its celebration of the introduction of the Catskill water, in October, 1917.

The value of his services to the Board of Water Supply is expressed in the resolution on his death, which reads as follows:

> "*Whereas,* Alfred D. Flinn, formerly department engineer, Headquarters department, and deputy chief engineer of the Board of Water Supply, departed this life on March 14, 1937, now, therefore,
>
> "*Be it Resolved,* that the Board of Water Supply expresses its deep sorrow at the death of Mr. Flinn, whose services to the City were vitally important in organizing the engineering bureau at the inception of the Catskill project and in designing the works and directing their construction.
>
> "*Be It Further Resolved,* that this resolution be spread on the minutes of the Board of Water Supply and that a copy thereof be transmitted to Mrs. Flinn."

Near the end of his service with the Board of Water Supply, Mr. Flinn became a Member of the Board of Direction of the Society and served on the Board of Engineering Societies Library. This was at the time of important changes in the Library, and as Chairman of a Special Committee, he investigated the various systems of classifications used in libraries and presented a plan for the re-organization of the Library, and the unification of the book collections of the several Societies into one well-arranged library.

On January 1, 1918, Mr. Flinn resigned from the Board of Water Supply to take up the most congenial work of his life with the several joint organizations of the Engineering Societies. In this position he was eminently successful; and he worked in it happily and untiringly until his health failed. One of the members of the 1918 Board of the United Engineering Societies who served two terms in this formative period, writes:

> "Flinn came as a godsend to us. * * * In the early years before Flinn's advent, we were constantly in difficulties. * * * Flinn's coming in to those Boards made a very different picture of it. The business and ef-

forts of those joint Boards went along much more smoothly than in the earlier days, and the 'Foundation' and the other organizations benefited very much."

The primary purpose in engaging the same person to be the executive officer of two or more organizations simultaneously was economy. No one of the organizations participating in joint arrangements could then afford a separate establishment. Operations were simplified and the work was reduced. For the Engineering Foundation and the Division of Engineering of National Research Council, the arrangement assured harmony of program and avoidance of duplication in closely related activities.

From January 1, 1918, to the time that his health began to fail in 1934, Dr. Flinn was Secretary (Executive Officer) of the United Engineering Society and its successors, Engineering Foundation, Inc., and United Engineering Trustees, Inc. The position entailed supervision of the Engineering Societies Building; execution and records of actions of the Board of Trustees, including administration of trusts and other funds; and secretarial services to standing and special committees.

He was Secretary of The Engineering Foundation from December, 1917, and Secretary and Director from 1922, until his death. He initiated or aided in developing and financing Fatigue of Metals Research (in co-operation with National Research Council), the Arch Dam Investigation, Alloys of Iron Research, Education Research Committee, including the pamphlet "Engineering: A Career—A Culture", smaller researches, assistance to special research committees of the Founder Societies, and organizations co-operating with them. His duties involved relationships with industries, universities, governmental bureaus, National Research Council, American Engineering Council, Society for the Promotion of Engineering Education, and other bodies, in all parts of the United States, and correspondence with other countries. The work included writing, compiling, or editing annual and special reports for the Foundation and its Committees, the Research Narratives in leaflet and book forms, Directory of Hydraulic Laboratories in the United States, and other publications.

In co-operation with National Research Council he aided in establishing the Personnel Research Federation, the Highway Research Board, the American Bureau of Welding, and in conducting the Marine Piling Investigation (damage to structures by marine borers), and compiling the Directory of Industrial Research Laboratories in the United States.

He was Secretary of the Engineering Council from January, 1918, to the time of its disbanding on December 31, 1920, to make way for the Federated American Engineering Societies, later known as the American Engineering Council. As such he dealt with "questions of general interest to engineers and to the public", some of which were activities incident to the World War and reconstruction, classification and compensation of engineers, uniform State law for "Registration of Architects, Engineers and Land Surveyors", improvement of the Patent Office, Engineering Societies Employment Bureau, and the National Public Works Department. An office was maintained at Washington, D. C., from January, 1919, to the disbanding of the Council.

He was connected with the Division of Engineering, National Research Council, as First Vice-President Chairman, November 1, 1920, to December 8, 1921, and then as Chairman until February 15, 1923, when he resigned. His activities included co-operation with The Engineering Foundation, other technical and scientific bodies, universities, industries, and governmental bureaus; and researches related to testing of hardness of metals and other substances, uses of tellurium and selenium, highways, welding, moulding sand for foundries, marine piling, pulverizing (of material for technical processing), electrical insulation, high-speed tool steels, heat transmission, applications of psychology and psychiatry to industry, rock drill steels, magnetic analysis, and phosphorus and sulfur in steel.

Dr. Flinn was Assistant Secretary of the John Fritz Medal Fund Corporation from January 16, 1920, until he resigned in October, 1935. He was elected Secretary and Treasurer of Daniel Guggenheim Medal Fund, Incorporated, on February 29, 1928. He resigned as Treasurer on May 3, 1935, and as Secretary on May 6, 1936. He served temporarily other bodies whose routine work was committed to United Engineering Trustees, Inc., from time to time, and only gave up these duties as ill health required.

Dr. Flinn received many honors for his work in engineering. The University of Louvain, Belgium, conferred the honorary degree of Doctor of Applied Sciences on him at its 500th Anniversary celebration in 1927, and the Worcester (Mass.) Polytechnic Institute, from which he had received his degree of Bachelor of Science in 1893, made him an Honorary Doctor of Engineering in 1932. He was an Honorary Member of the Masaryk Academy of Prague, and held other Czecho-Slovakian decorations.

He held membership in many societies, notably:

American Society of Civil Engineers (Director, 1917–1919);
American Institute of Mining and Metallurgical Engineers;
American Association for the Advancement of Science (Fellow);
American Mathematical Society;
American Iron and Steel Institute;
Municipal Engineers of the City of New York (Past-President); Gold Medal for the best paper of year.
Sigma Xi Scientific Fraternity;
The Century Association;
The Engineers Club of New York;
Masaryk Academy, Prague; Honorary Foreign Member of Section of Engineering Sciences;
Knight of the Order of the White Lion, Republic of Czecho-Slovakia;
Personnel Research Federation (Past-President and an organizer);
Engineering Societies Library Board, representing the American Society of Civil Engineers;
Boston Society of Civil Engineers, Librarian (honorary) for several years; re-organized and cataloged the Library and enlarged its collection;
National Research Council: Member of Executive Board for five years; Assistant Secretary (complimentary) as Secretary of the Engineering Foundation; Vice-Chairman and then Chairman of Division of Engineering; Vice-Chairman of Research Information on Service;
American Society for Testing Materials;
New England Water Works Association.

Dr. Flinn had always been interested in writing, and had a unique concise style which was easily recognized even though his name did not head the article. His hobby was to omit the article, "the," wherever possible. He never signed a letter "Yours very truly" and often omitted the salutation. He considered middle initials superfluous.

In 1911, he was requested by McGraw Hill Book Company to undertake a reference book on water-works. In this work, he recruited Robert Spurr Weston, and Clinton L. Bogert, Members, Am. Soc. C. E., and the late John H. Gregory, M. Am. Soc. C. E. Professor Gregory withdrew during the first year, but the other three authors worked together for five years producing the first edition. "Waterworks Handbook" is now in its third edition, and is used extensively in the United States and other countries. With characteristic modesty, Dr. Flinn inscribed the "Preface" as a compilation—not an original contribution to literature.

He was justly proud of his originating and editing for twelve years the Research Narratives published by The Engineering Foundation, which were widely circulated and reprinted in this and other countries.

Dr. Flinn was always considerate of the working hours of his assistants, but not of himself; he was a most persistent worker. It was his habit, before ill-health came, to be at his desk at home at 5:00 A.M., working for two hours at writing and editing before breakfast. In his early years, he kept Sunday free of his life work, but in later years, much of his time on Sundays was devoted to his absorbing writing of reports, and editorial work.

He was a pleasing and instructive public speaker. For two years in the Nineties he gave courses on water-works and water supply and on sewerage to Senior Classes of Lawrence Scientific School, Harvard University. On invitation, he gave the Chester S. Lyman Memorial Lectures on Conservation of Water by Storage, to the Senior Class, at the Sheffield Scientific School, Yale University.

From his youth, he was interested in church work, and during his residence in New York City he was a member of the Fifth Avenue Baptist Church.

In 1900, Dr. Flinn was married to Mary Brownell Davis, of Boston, who survives him. During the past year he sensed the impending summons, and sold his spacious home in Park Hill, Yonkers, and gave away most of his books and furniture, and retired to Heathcote Inn, Scarsdale, N. Y., where he died. His distribution of his belongings in this orderly manner, by gift rather than by sale, before his death, was thoroughly characteristic of the man.

He was noted for his logical presentation of facts, accuracy of statement, and thoroughness of detail. This characteristic went to the extent of leaving a concise summary of his activities from which this memoir is largely compiled.

Alfred D. Flinn was a Christian gentleman dominated by the highest ideals. His unfailing courtesy and thoughtfulness of others were outstanding characteristics. He worked unselfishly for the advancement of Engineers and the Profession of Engineering. His influence toward these objectives has been great, and will be more fully appreciated as passing years yield a better comprehension of his accomplishments.

Dr. Flinn was elected an Associate Member of the American Society of Civil Engineers on December 6, 1899, and a Member on May 2, 1905. He served as a Director of the Society from 1917 to 1919.

SIFROY JOSEPH FORTIN, M. Am. Soc. C. E.[1]

DIED MAY 16, 1937

Sifroy Joseph Fortin, the son of Jules and Sophie (Roy) Fortin, was born at Saint Sebastien, Iberville County, Province of Quebec, Canada, on May 6, 1867. Mr. Fortin's ancestors left France and settled in Canada about 1650.

After his preparatory schooling, which he completed at the Plateau Commercial Academy, in Montreal, Que., Canada, Mr. Fortin enrolled in the Civil Engineering Course at Laval University, the Applied Science Faculty of which is now the "École Polytechnique." He obtained his degree from this institution in 1889, at the same time winning the Governor General's Medal for the highest standing in his Class.

On leaving college, Mr. Fortin's first position was that of Inspector on the construction of the Lachine Aqueduct, which supplies water to the City of Montreal. From February, to December, 1890, he was engaged as Draftsman with Livering and Garrigues, Civil Engineers and Contractors, of Philadelphia, Pa.

In December, 1890, he joined the Staff of the American Bridge Company and continued with that Company until January, 1892, working on the detailing, design, and estimating of structural steelwork for bridges and buildings. Mr. Fortin was then employed for a short period with the Riverside Bridge Works, in New Jersey, and, later, became Assistant to the late Charles O. Brown, M. Am. Soc. C. E., Consulting Engineer and Contractor, of Brooklyn, N. Y., where he had charge of the estimating and drafting-room and made the calculations, under Mr. Brown's supervision, for the following structures: Manhattan Life Building, 17 stories and tower (cost, $1 000 000); Empire Building, 22 stories (cost, $2 000 000); addition of 6 stories to Standard Oil Building (cost, $1 000 000); and a number of smaller structures, including an armory in New York, N. Y. During the latter period of his engagement with Mr. Brown, he helped him with the revision of the sections on steel, concrete, and foundations in the Building Code of the City of New York.

In 1899, Mr. Fortin joined the Milliken Brothers, Civil Engineers and Contractors, of New York City, with which firm he remained until 1914, a period of fifteen years. He represented this Company in various parts of the world, spending two years in Hawaii, two years in China, Japan, and The Philippines, and eleven years in Mexico.

---

[1] Memoir prepared by Vernon R. Davies, Esq., Westmount, Montreal, Que., Canada.

In Hawaii he prepared the specifications, obtained the contracts, and supervised the erection of six large sugar refineries. His Company having next successfully negotiated contracts with the Russian Government for the steelwork in the arsenal, and dry dock and ship-repairing plant, at Port Arthur, China, Mr. Fortin proceeded to China where he supervised the completion of the design and took charge of the erection for the owners. The benefits to his Company's clients were of short duration because, about two years after Mr. Fortin's departure from China, the Russo-Japanese War broke out and the greater part of these works were destroyed by the bombardment of this city.

Upon leaving the Orient, Mr. Fortin next negotiated, for his firm, the contracts with the Mexican Federal Government for the steelwork in the following buildings: Post Office (estimated cost, $1 000 000); War and Navy Building ($1 800 000); The National Theatre ($4 000 000), not finished until later; and the Federal Legislative Palace or Parliament Building (estimated cost, $10 000 000), which was not completed. Mr. Fortin prepared the plans for, and supervised the steelwork in, these buildings.

During the period of his residence in Mexico as Representative of Milliken Brothers, his Company acted as Government engineers under President Porfirio Diaz's régime. The Mexican Government assigned to them the task of preparing plans and specifications for the steelwork and reinforced concrete, foundations, and other structural details for various public undertakings. Several collateral contracts covering fireproofing and roofing were also obtained and carried out for the Mexican Government. In addition to the Government's contracts, Mr. Fortin also obtained for his firm some large contracts from private individuals and corporations in Mexico for the building of car sheds, sugar refineries, bridges, and other structures.

The construction of the Parliament Buildings, in the City of Mexico, offered a special problem in foundations due to the nature of the sub-soil, which is a volcanic ash possessing a low bearing value. A system of foundations developed by Mr. Fortin was accepted by the Ministry of Transportation and Public Works and, later, formed the basis of a monograph entitled "Novel System of Foundations Used in Connection with the Federal Legislative Palace, Mexico City." [2]

The Revolution which broke out in Mexico in 1914 caused the suspension of all work upon which Mr. Fortin was engaged, and he returned to Canada to become Structural Engineer for the Public Works Department in Ottawa, Ont. This position he held until 1918, during which time he was engaged on the construction of railway and highway bridges, steel and wooden terminal freight sheds, dry-docks, wharves, dams, and hydraulic projects. The works undertaken included bridges at Kingston, Ont., Ottawa, and Riviere-des Quinze, Que.; dry-docks at Halifax, Nova Scotia; Levis, Que.; and Esquimalt, B. C.; sheds at Halifax, St. John, N. B., and Vancouver, B. C.; in addition to docks and dams throughout Canada.

Mr. Fortin left the Government Service in September, 1918, to become Deputy Director and Deputy Chief Engineer of the Public Works Department of the City of Montreal. His duties included the general supervision of all engineering projects undertaken by the City connected with the Roads Division, sewers, and municipal shops.

---

[2] *Transactions*, Canadian Soc. of Civ. Engrs., Vol. III, 1916.

In April, 1922, he was called upon to form the Technical Commission and became its first Chairman. In the same year he was appointed to the Water Board. One of the functions of the Technical Commission was the development of a town planning scheme for the City, and Mr. Fortin incorporated his studies in this connection into a monograph entitled "Considerations on a Plan of Organization and on Functions of a Town Planning Commission for the Island of Montreal." [3]

In September, 1930, he became Consulting Engineer to the Executive Committee of the City of Montreal, and in the same year he revived the Technical Commission which had previously lapsed. This Commission was composed of seven specialists, with Mr. Fortin acting as Secretary. He carried on with these duties until his retirement in 1935, due to failing health. He died two years later at the age of 70 yr.

Mr. Fortin was a member of the Engineering Institute of Canada, the Corporation of Professional Engineers of Quebec, and the Association des Anciens Eleves de l'École Polytechnique. He was a life member of the Board of Governors of l'École Polytechnique, and a member of the Marlborough Golf and Country Club.

On June 14, 1894, he was married to Maria Graziella Lalonde, who survives him. He is also survived by an only child, Gaston L. Fortin, Civil Engineer.

Mr. Fortin's great diversity of interests won for him a wide circle of friends. He had a very intimate knowledge of the French and English languages and literatures and also a very thorough knowledge of Spanish. His principal hobby was the collection of records relating to the early history of the French in Canada, and particularly those records relating to the history of his own family, which he incorporated into a brochure which was printed a short time before he died.

Mr. Fortin was elected an Associate Member of the American Society of Civil Engineers on November 6, 1895, and a Member on December 6, 1904.

ABRAHAM GETMON GIDEON, M. Am. Soc. C. E.[1]

DIED DECEMBER 17, 1936

Abraham Getmon Gideon was born in Tula, Russia, on July 1, 1871, the son of Myron O. and Reba (Rubens) Getmon Gideon. When Mr. Gideon was a boy, railroad construction near the town of his birth aroused in him an interest in Engineering, which later took him to the United States. He was graduated from Cornell University, at Ithaca, N. Y., in Civil Engineering and also attended Law School for two years. His scholastic record was outstanding.

---

[3] *Revue Trimestrielle,* and the *Engineering Journal of Canada,* 1924.

[1] Memoir prepared by Paul W. Mack, Assoc. M. Am. Soc. C. E.

Mr. Gideon began his engineering career in Little Falls, N. Y., under Stephen E. Babcock, City Engineer, in the branch (water-works) of engineering which he followed all his life.

From 1900 to 1902, he was Assistant Engineer and Engineer in charge of design, specifications, etc., of the drainage and sewerage systems of Havana, Cuba. His work there was the foundation of important subsequent work in the Philippine Islands.

He spent one year with Westinghouse, Church, Kerr, and Company, on the design and investigation of a hydro-electric plant on the Housatonic River, and from there he went to Manila, Philippine Islands, in 1905. For twenty-five years, he devoted his engineering ability to the problems of the water supply and sewerage of Manila. Mr. Gideon designed the storm drains and was Superintendent of Water Supply and Sewers, and, from 1910 to 1919, he was Chief Engineer of the Department of Sewers and Water-Works. In 1919, he served as Consultant to the Quartermaster, United States Army, on the water supply of the fortifications on Corregidor Island and designed the water supply system for Fort Stotensburg.

Mr. Gideon had the confidence of the late Governor General Leonard Wood, and during the World War acted as City Engineer of Manila. He saw the need of changing the municipal Water Department to a Metropolitan Water District. Governor General Wood approved of the change and appointed him to be the first Manager. His financial ability turned the annual deficit of the Water Department to a surplus of the Metropolitan Water District, and an enlarged supply was planned and financed. He saw this work well on the way to completion before his retirement.

Mr. Gideon was a Director of the Philippine National Bank and the Bank of the Philippine Islands, the Philippine Railroad Company, and the Manila Hotel. He was a member of the Army and Navy Club, the Casino Espanol, and a Thirty-second Degree Mason.

He is survived by his widow, Mrs. Edith Mary Gideon, and a son, David of Oakland, Calif.

Mr. Gideon was elected an Associate Member of the American Society of Civil Engineers on September 3, 1902 and a Member, on November 1, 1910.

WILLIAM JOHNSON HARAHAN, M. Am. Soc. C. E.[1]

Died December 14, 1937

William Johnson Harahan was born in Nashville, Tenn., on December 22, 1867, the son of James Theodore Harahan, late President of the Illinois Central Railroad Company, and Mary B. (Kehoe) Harahan. The family moved to New Orleans, La., soon after he was born, and it was there that he received his primary education, and was graduated from St. John's College, in 1885, at the age of seventeen. He had worked as shop apprentice, and in various other minor positions, for the Louisville and Nashville Railroad Company, during his college vacation periods, starting in 1881, when he was fourteen years old. Upon graduation he began working regularly for the Louisville and Nashville Railroad Company, and from that time until his death he was engaged continuously in railroad work.

---

[1] Memoir prepared by a Committee of the Cleveland Section, consisting of William Michel and Leonard B. Allen, Members, Am. Soc. C. E.

Father and son spanned almost three-quarters of a century of railroading. For twenty-five years, they worked on the same railroads together, much of the time side by side. Almost the complete history of railroad transportation may be told in the span of years served by the Harahans. The elder Harahan started his career on the old Virginia Midland Railroad, later part of the Southern Railroad System, in 1864, in the most devastating period of the war between the States.

Mr. Harahan spent more than fifty-two years working with railroads. They were his work and his play. This devotion, and his outstanding ability, together with a natural heritage from his father, made him one of the greatest railroad men in the United States. He built several thousand miles of new railroads and additions to existing railroads, and was in charge of other large construction work for many years, including the building of a number of large bridges over important streams.

He worked in various minor capacities on the Louisville and Nashville Railroad, from 1885 to 1886, and from 1886 to 1889, he was in the Engineering Department of the same Railroad Company as Chainman, Transitman on Location, and Assistant Engineer.

In 1889, when he was twenty-two years of age, Mr. Harahan was appointed Division Engineer of the Cincinnati Division of the Chesapeake and Ohio Railway Company. One of the first tasks assigned to him in that capacity was the repair of the damage wrought by an Ohio River flood. That experience was to be of practical help to him in the recurrence of flood conditions on the Chesapeake and Ohio Railroad in later years, including the floods of 1936 and 1937.

In 1890, he received appointment as Superintendent of Structures of the Baltimore and Ohio Southwestern Railroad Company. In 1892, he became Roadmaster and Trainmaster of the Illinois Central Railroad Company, and progressed rapidly to be Superintendent, Chief Engineer, Assistant General Manager, and General Manager. In 1905 he was appointed Fourth Vice-President, in charge of Traffic and Engineering. In 1907, Mr. Harahan relinquished the Illinois Central Vice-Presidency and accepted appointment as Assistant to the President of the Erie Railroad Company, remaining in this position until January, 1911, when he was elected Vice-President in charge of Engineering. In September, 1912, Mr. Harahan was elected President of the Seaboard Air Line Railroad Company and served in this office until 1918. Between 1918 and 1920—the Federal Control period—he was Federal Manager of the Seaboard Air Line. From April to December, 1920, he served the Director General of Railroads as a Staff Officer. In December, 1920, he was elected to the Presidency of the Chesapeake and Ohio and Hocking Valley Railway Companies and served these roads in that capacity until May, 1929, when impaired health prompted him to give up this post to become Senior Vice-President of the two railroad companies, and also of the Pere Marquette Railroad Company. The late J. J. Bernet, who succeeded Mr. Harahan to the Presidency of the Chesapeake and Ohio and Hocking Valley Railway Companies in 1929, died in 1935. Improved in health by that time, Mr. Harahan was prevailed upon to resume the Presidency of the Chesapeake and Ohio Railroad Company, and, at the same time, take upon his shoulders the responsibilities of the same office for the New York, Chicago and St. Louis Railroad Company (Nickel Plate Road) and Pere Marquette Railroad Company. The Hocking Valley had lost its identity in 1930 when it was merged with the Chesapeake and Ohio Railroad Company.

In addition to being President and a Director of each of the three railroads at his death, Mr. Harahan was also a member of the Board of Directors of the Erie Railroad.

During his first tenure as President of the Chesapeake and Ohio and Hocking Valley Railway Companies, Mr. Harahan developed an executive personnel that was to become recognized as one of the most efficient in the railway field. He had a faculty of appraising ability. He liked to encourage talent and reward achievement. The organization as it is to-day is of his making, for Mr. Bernet, on assuming direction of the roads, was surprised at the proficiency he found in all departments and made no changes. What he thought of it was perhaps best summed up in his comment that, "the road is so well run it seems to run itself."

At the inception of Mr. Harahan's administration, the Chesapeake and Ohio Railway did not have a physical connection with its subsidiary, the Hocking Valley Railway, its outlet for coal moving to Great Lakes ports. This physical connection was supplied in 1927, through the construction, under Mr. Harahan, of a 63-mile double-track line between Greeg and Valley Crossing, from Columbus to Waverly in Southern Ohio, without grade crossings (with one exception), and with ideal ruling grades. The line was completed in ten months, an all-time record in American railroad construction.

Physically and financially, in the period from 1923 to 1929, the road underwent transformation and acquired a recognized status as one of the world's most efficient transportation machines. Its sphere in the marketing of coal, once narrowly circumscribed, was expanded East and West, North and Northwest, through affiliations that were provided with such related lines as the Nickel Plate Road, the Pere Marquette, and the Erie.

Mr. Harahan's instincts were scholarly. He read the Classics. He had a definite liking for history. Apart from a fondness for baseball, reading seemed to be his only hobby.

On the personal side, Mr. Harahan lived quietly and unpretentiously, and as a devoted husband and father. He was married twice. His first wife was Susannah M. Smith, of Nashville, Tenn., to whom he was married in 1890 and by whom he had twelve children. Following the death of his first wife, he was married on March 23, 1935, to Mrs. Elizabeth M. Smith. They resided at Wade Park Manor, Cleveland, Ohio.

Mr. Harahan's pride, and the source of his greatest happiness, was his large family of children, comprising his own by his first wife, along with the children of his widowed sister, whom he adopted, and some other orphaned children, not related to him, whom he reared. At one time, the children numbered as many as twenty-one. The dining rooms in the Harahan homes at Chicago, Ill., and at Norfolk, and Richmond, Va., before the children grew up, had to be quite extensive.

Besides his second wife, and her son by a former marriage, Thomas W. Smith, he is survived by eight children of his first marriage, including three sons: James Theodore II, William Johnson, Jr., and Joseph Patrick; and five daughters: Mrs. Louis Moquin and Mrs. Richard Markey, Catherine Agatha, Virginia Mary (Sister Catherine Virginia of the Sisters of Notre Dame), and Theodora Margaret Harahan. He was also survived by a brother, J. T. Harahan, Jr., and two sisters, Mrs. A. H. Effinger, and Mrs. Theodore H. Templeton.

A devout Churchman, Mr. Harahan interested himself actively in Catholic charities. He was Vice-President of the Society for the Propagation of the Faith of the Diocese of Richmond, Honorary Vice-President of the Catholic Conference on Family Life, Director of the National Council of Catholic Men, and a member of the Knights of Columbus.

He was a member of the American Railway Guild, Railroad Club of New York, Midday Club (New York), Union League (Chicago), the Country Club of Virginia, the Commonwealth Club, and the Westmoreland Club, of Richmond.

Mr. Harahan was elected an Associate Member of the American Society of Civil Engineers on October 3, 1894, and a Member, on October 7, 1903.

LEWIS MUHLENBERG HAUPT, M. Am. Soc. C. E.[1]

Died March 10, 1937

Lewis Muhlenberg Haupt was born in Gettysburg, Pa., on March 21, 1844, the son of General Herman Haupt, M. Am. Soc. C. E., Scientist and Engineer, and Builder of Military Roads and Bridges during the Civil War, and his wife, Anne Cecilia (Keller) Haupt.

He studied at the Lawrence Scientific School of Harvard University, at Boston, Mass.; and in the autumn of 1863 he was appointed by President Lincoln to the United States Military Academy, at West Point, N. Y. He was graduated, in 1867, with the rank of Second Lieutenant, United States Corps of Engineers.

---

[1] Memoir prepared by Charles E. Billin, M. Am. Soc. C. E.

Lieutenant Haupt's first work in the Service was with a party conducting the triangulation of Lake Superior and the "on-shore" line survey and "off-shore" hydrography of the Lake and of St. Marys River. In 1868, he was appointed Engineer Officer of the Fifth Military District of Texas.

In 1869 Lieutenant Haupt resigned from the Army Engineer Corps to accept the position of Assistant Engineer and Topographer in charge of the surveys of Fairmount Park, in Philadelphia, Pa., in which position he collected data for an elaborate map, located and constructed drives, drains, and other engineering features of this extended pleasure ground.

He was intimately associated with Philadelphia and its civic developments. He soon became interested in the traffic problems of the City, current and future, putting forward the claims that the corner of 33d and Market Streets was the most suitable site for a Union Rail Terminal—a project for which the facilities now exist but which still awaits realization. As early as 1877 he proposed that diagonal streets be cut through from City Hall so as to facilitate the movement of highway traffic.

In 1872, Mr. Haupt was appointed to the Technical Staff of the University of Pennsylvania, at Philadelphia, Pa., as Instructor in Mathematics and Drawing. In 1873, he became Assistant Professor of Civil Engineering, and continued in that capacity until 1875, when he was advanced to be Professor of Civil Engineering, which position he held until 1892.

His extended experience gave him practical knowledge as an Instructor. He had the vision to stimulate earnestness and invention in his students and make them realize the importance of their work. His long summer vacations were spent in practical engineering work, thus giving him a constantly increasing store of experience to draw upon in his teaching. His students were often given the opportunity to help him in these undertakings.

In 1873, his second year at the University, Professor Haupt made the first survey for range lights on the Delaware River, the students working with him, thus bringing them into actual contact with the problems of the times and giving them a working efficiency unattainable by more abstract methods of instruction.

For five years he was also Assistant with the United States Coast and Geodetic Survey in charge of the triangulation of Pennsylvania. His students will remember how, in 1875, they worked with him in determining fixed points on the ground for accurate surveys for latitude, longitude, boundary lines, railroads, etc., and thus, through all the succeeding years of his connection with the University, he worked to make the Department of Civil Engineering rank among the first with those of the most eminent institutions in America. In 1883, the University of Pennsylvania conferred on Professor Haupt the Honorary Degree of Master of Science.

Beginning in 1893, he devoted his time quite fully to the subject of economy in transportation, giving especial attention to deepening the coastwise system of canals. In 1894, he was selected as Engineer in Charge, by the Canal Commission of Philadelphia, to make the surveys and report upon a ship canal between Philadelphia and the sea, across New Jersey. He was also chosen by the Provisional Committee of Pittsburgh, Pa., to report on a ship canal between that city and Lake Erie.

Professor Haupt was frequently consulted in matters pertaining to the economics of transportation, particularly the utility of deep-water canals, and was also called upon to take an active interest in some of the great enterprises of the Western Continent. In 1897 he was appointed by President McKinley to study the feasibility of a canal linking the Atlantic and Pacific Oceans, *via* Nicaragua. He advised such a site, but eventually the Panama site was selected; and, later, he was appointed to the Panama Canal Commission.

Although engrossed in these vast enterprises, he found time to write extensively on technical subjects. He was the author of a number of publications relating to the economies of transportation and the improvement of navigable channels by the utilization of the forces of Nature.

Professor Haupt devoted much time to the problems of beach and harbor protection, with special attention to jetties and to the automatic deepening of harbor entrances. He studied all the major ship canals in the United States and many abroad. In 1887, he patented the Reaction Breakwater, utilizing the forces of tide-water itself to clear and maintain the channel, a principle which has been widely adopted. Of equal utility was his later invention of the "hooked jetty" designed to check coastal erosion. For these inventions he received the highest award at the National Export Exposition, in Philadelphia, in 1899. Their great utility, economy, and efficiency were demonstrated at Aransas Pass, Texas, in 1895 to 1907 as a purely tidal inlet. His inventions were endorsed by experts and engineers throughout the country.

The Elliott Cresson Gold Medal and Premium of the Franklin Institute, in Philadelphia, the highest award within its gift, was presented to Professor Haupt in 1901 for "Improvements in Methods of Removing Ocean Bars." These inventions also won for him the Gold Medal of the Louisiana Purchase Exhibition in 1904.

In 1887, for his paper on the "Physical Phenomena of Harbor Entrances," and for his invention of a system of harbor improvements, he was awarded the Magellanic Premium by the American Philosophical Society—the highest acknowledgment that is in the power of that Society to bestow, and an honor which has been conferred only twice in the last forty-five years.

Combined with another development he used the installation of a double row of open pilings, which device has resulted in the recovery of many acres of beach front at Far Rockaway, Long Island, N. Y., and at many points along the New Jersey Coast.

The writer's acquaintance with Professor Haupt began in 1877 when he was unanimously elected the first President of the Engineers' Club of Philadelphia, at its organization meeting on December 17 of that year. On March 14, 1916, he was elected to Honorary Membership in the Club. The Club owns many of his papers on subjects relating to river and harbor improvements, such as the removal of Smith's Island in the Delaware River, directly opposite Philadelphia; inter-communication of cities; and others covering a wide range, for his pen was an active one.

Professor Haupt published many scientific works, including "Engineering Specifications and Contracts," "The Physical Phenomena of Harbor Entrances," "Canals and Their Economic Relation to Transportation," and "A Move for Better Roads."

He was a member of the American Philosophical Society, National Geographic Society, American Historical Society, American Association for the Advancement of Science, The Franklin Institute of Philadelphia, and The Engineers Club of Philadelphia.

Professor Haupt's personality was most attractive; he was energetic, always genial, and a great favorite with his students and his professional and social friends. Although it is conceded that it requires brains and ability to accomplish great things in life, still it is equally true that even brains and ability will not accomplish much without energy and opportunity.

His life was one of great achievement, backed by ability and pushed forward by energy. His record is an example, and should be an inspiration, to every young engineer.

On June 26, 1873, he was married to Isabella Christiana Cromwell, who died on December 21, 1912. He is survived by four daughters and one son.

Professor Haupt was elected a Member of the American Society of Civil Engineers on June 6, 1888.

WYATT SWIFT HAWKINS, M. Am. Soc. C. E.[1]

Died July 15, 1937

Wyatt Swift Hawkins was born on December 18, 1876, in Hannibal, Mo. He was the son of Judge Thomas W. Hawkins and Anna Belle (Newland) Hawkins. When he was quite young the family moved to Palmyra, Mo., where he attended the local schools, and Centenary College. Although he was not a graduate of the College, he completed practically the full course of study.

After leaving college, Mr. Hawkins went to what was then Indian Territory, later the State of Oklahoma, in the service of the United States Geological Survey and was employed as Field Assistant and Surveyor until that work was completed in 1899. He was then assigned to the Commission to the Five Civilized Tribes and was in charge of the allotment to the Creek and Seminole Indians. In 1906, he was transferred to the service of the Commission of Indian Affairs and made Chief Engineer of the Osage Indian Reservation having charge of the complete re-survey of the reservation.

Immediately, thereafter, he was appointed State Engineer of Oklahoma, under Governor Haskell, and served with him until the close of his administration. From 1908 until 1910, Mr. Hawkins was a Special Engineer with the Missouri, Kansas and Texas Railroad Company, on the design and estimate work connected with the raising of all the tracks to an elevation above high water. This work involved the expenditure of about $14 000 000. In 1910, he went into private consulting work in Oklahoma and Texas and engaged in municipal work and road and bridge design.

---

[1] Memoir prepared by Davis K. Jackson, Esq., Jefferson City, Mo.

In 1913, he was called back to Missouri by Governor Major to take the position of State Highway Engineer and Deputy Commissioner of Missouri, and he served in this capacity throughout the Governor's term. In 1915, he returned to Durant, Okla., where he again entered the practice of engineering, acting as consultant on many municipal projects in that area.

While essentially a peace-loving man he offered his services to his country in the spring of 1917, and served as Captain with the 55th Regiment of Engineers until 1919, having fifteen months overseas duty. His time in the Army was devoted mainly to road and railway construction and this was especially true in regard to his service overseas.

At the conclusion of his period of Army service Mr. Hawkins again returned to Durant, and the private practice of engineering, specializing in municipal work. In 1922, he moved to Greenwood, Miss., where he was the Consultant on a program involving the expenditure of $850 000 for public improvements. In 1925, he moved to Gulfport, Miss., where he was the Engineer on the Harrison County road and bridge program, involving an expenditure of $3 176 000; the Biloxi, Miss., $335 000 paving program; the $140 000 general improvement works in Pass Christian, Miss.; and a $5 000 000 project at Gulf Hills, Miss., as well as many smaller projects in that area. He supervised more than $10 000 000 worth of work in Mississippi alone.

At the conclusion of this work in 1929, he received the appointment as an Engineer of Special Assignment with the Missouri State Highway Department. At this time, Missouri was just inaugurating its "Farm-to-Market" program, and Mr. Hawkins' position involved the selection of various routes over the State. He was especially well fitted for such work due to his wide experience in road design and construction. With the inception of the Federal Emergency Relief Administration he was placed in charge of all such projects being handled by the State Highway Department, and continued in charge when that work was transferred to the Works Progress Administration. In September, 1935, he was appointed to the post of Division Engineer of Division No. 3 of the State Highway Department, and returned to his old home in Hannibal. He served in this capacity until his death. His life was an example of complete devotion to his family, friends, and work.

Although ill during a greater part of the last year of his life, he seldom missed a day at the office to see that everything was running smoothly. It has been justly said that there was no man in the Highway Department who was more popular nor who had more friends. He took a special interest in his subordinates. An Elder in the Presbyterian Church, he was always active in its circles.

On May 17, 1898, he was married to May Colbert, of Oklahoma (at that time Indian Territory) who survives him, with three daughters, Mrs. Ragan B. Jones, Mrs. J. M. Garrison, and Mrs. Emory Lampkin. Two brothers, Robert N. Hawkins and Alfred L. Hawkins, also survive him.

Mr. Hawkins was elected a Member of the American Society of Civil Engineers, on June 6, 1927.

HARRY MONMOUTH HERBERT, M. Am. Soc. C. E.[1]

Died October 6, 1937

Harry Monmouth Herbert was born at Monmouth Battle Ground, Monmouth County, N. J., on January 31, 1857, the son of Major Jacob Van Wickle Herbert and Eliza Jane (Smock) Herbert.

He received the degree of Bachelor of Science from Rutgers University, at New Brunswick, N. J., in 1878, and the degree of Master of Science in 1881.

Mr. Herbert was Assistant Engineer, with the United States Army, under the late General John Newton, U. S. Army (*Retired*), Hon. M. Am. Soc. C. E., from 1878 to 1883, in which capacity he was employed on surveys at Elizabethport, and Raritan River, N. J., and the Gowanus Canal in Brooklyn, N. Y.; in charge of the dredging and diking on the Raritan River, and of dredging at Gowanus Bay and Buttermilk Channel, in New York Harbor.

From 1884 to 1885, he was Assistant Engineer on topographical surveys and on the location of railroad lines at and near Lake Hopatcong, Greenwood Lake, and Barnegat Beach, in New Jersey; from 1885 to 1886, he was Assistant Engineer on the location of the Pennsylvania, Slatington, and New England (later the Pennsylvania, Poughkeepsie, and Boston) Railroad, between Slatington, Pa., and Washingtonville, N. J., and also on the location of about fifteen miles of the Bloomsburg and Sullivan Railroad in the vicinity of Ganoga Lake.

From 1887 to 1893, Mr. Herbert was Resident Engineer for the Lehigh Valley Railroad Company. The following work was done under his supervision: Construction of the main line between South Plainfield, N. J., and Newark, N. J.; location and construction of the Perth Amboy and Raritan River Branch; monumenting the line and right of way from Newark and Perth Amboy to Easton, Pa.; and the rebuilding of nearly all the bridges on the Easton and Amboy Division.

In 1893, Mr. Herbert had general engineering offices at Bound Brook, N. J., and was Borough Engineer of Bound Brook from 1893 to 1895, during which time he designed and built the sewerage system there; designed and built the extension to the Roselle, N. J., sewers; designed a sewerage system for Lambertville, N. J., as well as a system for East and North Somerville, N. J., and a system of water supply for Middlebrook Heights, N. J.; designed a water supply for South Bound Brook, N. J.; and, with Louis Focht, Assoc. M. Am. Soc. C. E., designed a sewerage system for Flemington, N. J.

---

[1] Memoir prepared by William H. Boardman, Esq., Philadelphia, Pa.

From December, 1896, to December, 1898, he was Chief Engineer of the New York and Philadelphia Traction Company, in which capacity he located and made plans and specifications for more than 25 miles of line.

From 1898 to 1900, Mr. Herbert was Director and Chief Engineer of the American Engineering Company, which Company built, equipped, and placed in operation the following electric railways: Newtown, Pa., Street Railway; The Elmira and Seneca Lake Railway; and a line between Battle Creek, Mich., and Kalamazoo, Mich., for the Michigan Traction Company.

As Contracting Engineer from 1901 to 1904, he built, equipped, and placed in operation the Philadelphia and Easton Railway, a high-speed electric railway between Doylestown, Pa., and Easton.

On April 12, 1906, Mr. Herbert was appointed a member of the State Sewerage Commission of New Jersey by Governor Stokes. The powers and duties lodged in the State Sewerage Commission were vested in the Board of Health of the State of New Jersey by an Act which became effective on April 16, 1908. Mr. Herbert was appointed Chief of the Division of Sewerage and Water Supplies of the State Board of Health on May 26, 1908.

He resigned from the aforementioned position on May 2, 1911; and on June 2, 1911, he was appointed Chief Engineer of the Camden, N. J., Water Department, where he remained until 1913. He then returned to Bound Brook and resumed private practice in hydraulic and sanitary fields. He was appointed Borough Engineer of Bound Brook in 1918 and served until 1925.

He was later appointed Borough Engineer of Seaside Heights, N. J., where he inaugurated many municipal improvements, including a sewerage system and sewage disposal works, and extensions and improvements to the water supply.

Mr. Herbert established a reputation as one of the foremost engineers in hydraulic and sanitary work, and was relentless in his fight to guard the public health. He was held in the highest esteem by his associates for his personal probity and business integrity.

Mr. Herbert was married in November, 1891, to Ella Tucker, of Bound Brook, who survives him, as does a daughter, Mrs. Norman J. Elmes; two grandchildren, Anita and Norman J. Elmes; and a sister, Emma S. Herbert.

He was a member of the following organizations: Society of American Military Engineers; American Water Works Association; American Public Health Association; and Past-President of the New Jersey Sanitary Association.

Mr. Herbert was elected a Member of the American Society of Civil Engineers on April 6, 1898.

NICHOLAS SNOWDEN HILL, JR., M. Am. Soc. C. E.[1]

Died October 18, 1936

Nicholas Snowden Hill, Jr., was born in Baltimore County, Maryland, on June 18, 1869, the son of Major Nicholas Snowden Hill and Mary (Cocke) Hill. He was graduated from Stevens Institute of Technology, at Hoboken, N. J., in 1892, with the degree of Mechanical Engineer.

Mr. Hill entered professional life as Mechanical Engineer for the South Side Elevated Railroad, in Chicago, Ill., in 1892. The following year, he returned to Baltimore, Md., to serve as Engineer-Secretary of the Baltimore Sewerage Commission, for which Commission he formulated a report which served as a basis for the existing sewerage system of Baltimore. Later, he was appointed Engineer of the Electrical Commission of Baltimore and designed an underground conduit system for the accommodation of all the electrical wiring of the city, the first comprehensive underground conduit system in the United States. Following this, Mr. Hill was made Chief Engineer of the Water Department of the City of Baltimore, and in this capacity, he re-organized the Department and designed and supervised extensive improvement to the water-works system.

In 1898, he left Baltimore to become Chief Engineer of the Charleston (S. C.) Consolidated Railway, Gas, and Electric Company and as such he was active in the consolidation of that Company's various properties and rebuilt and rehabilitated them.

After the completion of this work, Mr. Hill was appointed Chief Engineer of the Water Department of the City of New York, N. Y. As Executive of the Department he was in responsible charge of improvements amounting to several millions of dollars annually, and instituted a comprehensive investigation of the ground-water supplies of Long Island.

In 1903, Mr. Hill resigned as Chief Engineer of the Department to establish a private engineering practice, and continued as a Consulting Engineer with offices in New York City until his death. As such, he gave special attention to problems of water supply and sanitary engineering, and to public utility appraisals, being recognized as one of the foremost experts in the field of public utility valuations.

In his consulting engineering work he established an international reputation, and was identified with notable enterprises in the United States, Canada, Mexico, Cuba, and China. During his professional life he was retained by more than three hundred and fifty States, districts, counties, municipalities, and private corporations, and he appraised more than one hundred water companies and departments.

Some of the more notable projects and problems with which Mr. Hill was associated in his capacity as Consultant were: Member of a committee of three engineers to study and report on the pollution of harbors along the

---

Atlantic seaboard; a report on the Bronx Valley Sewer Project for the Bronx Valley Sewer Commission, of Westchester County, New York; Chairman of the Jerome Park Filter Commission to consider the advisability of filtering the Croton Water Supply for New York City; Consulting Engineer for Jersey City, N. J., regarding the proper method of treating the Jersey City Water Supply; a report on additional water supply for the City of Baltimore; a comprehensive report on water supply, drainage, sewerage, and sewage treatment for Tampa, Fla., and environs, and the design and supervision of construction of new water supply system; collaboration on investigation and report upon available new water supplies for Regina, Saskatchewan, Canada, and surrounding communities; a survey and report on water supply resources and water supply conditions throughout Westchester County and the best means of developing and organizing a county controlled system; a complete and comprehensive report for the City of Albany, N. Y., on sources of water supply available and recommended development; Consulting Engineer to the New Jersey Water Policy Commission, including study and investigation of the best means of developing and conserving the water resources of the State, and a comprehensive survey of resources and requirements; a report on the development of a water supply for the Metropolitan District of Northern Ohio; testimony for the State of New Jersey in the Delaware diversion case before Special Master appointed by United States Supreme Court; and investigation and report on water supply and financial administration of the Shanghai, China, Water Works Company, Limited.

During the World War Mr. Hill was Supervising Engineer of Camp Merritt, New Jersey, and Designing and Supervising Engineer for the United States Housing Bureau in connection with its developments at Norfolk and Portsmouth, Va.

Among his outstanding designs in the field of water-works engineering is the Oradell Dam, of the Hackensack, N. J., Water Company. He was awarded the Thomas Fitch Rowland Prize of the Society in 1926 for his paper on the design of the Oradell Dam.[2]

Mr. Hill served as President of the Board of Water Commissioners of East Orange, N. J., from 1912 to 1920, and as President of the Consolidated Water Company of Suburban New York from 1921 to 1923. He was closely associated with the Hackensack Water Company, serving about fifty odd communities in Northern New Jersey. He acted as Consulting Engineer for this Company from 1910, as Director from 1922, and as President from 1926.

He was an Honorary Member and Past-President of the American Water Works Association, and donor of the Nicholas S. Hill, Jr., Cup; a former member of the Council of the American Institute of Consulting Engineers; Chairman and member of several important technical committees; and the author of numerous technical papers.

He was a member of the following technical societies: American Institute of Consulting Engineers (Member of Council; and Chairman, Committee on Professional Practice and Ethics); American Society of Mechanical Engineers (Membership Committee; and Standardization Committee and Sub-

Committees); American Society for Municipal Improvements (Chairman, Committee on Water-Works); American Water Works Association (Honorary Member; President 1915–1916; Chairman, Committees on Private Fire Protection; Electrolysis and Electrical Interference; and Water Quality and Water Treatment; Committee on Collection of Material and "Manual of Water Works Practice"; and Committee on Diven Memorial); American Society for Testing Materials (Committee on Cast Iron); American City Planning Institute; American Electrochemical Society; National Conference on City Planning; National Municipal League; International City Managers Association; American Committee on Electrolysis (Representative of American Water Works Association); American Committee on World Power Conference; Committee on Standardization of Pipe Fittings and Flanges; New England Water Works Association; Connecticut Society of Civil Engineers; New England Sewage Works Association; New York Sewage Works Association; New Jersey Sewage Works Association; Municipal Engineers of the City of New York; American Association for the Advancement of Science; and American Academy of Political and Social Science. He was also an Associate Member of the American Institute of Electrical Engineers, and a Fellow of the American Health Association (Committee for Public Health Engineering Section).

Mr. Hill was a member of the following non-technical organizations: American Child Hygiene Association; National Economic League; National Geographic Society; Metropolitan Museum of Art, New York City; Merchants Association of New York City (Committee on Sanitation); and Bergen County, New Jersey, Chamber of Commerce (Executive Committee).

He also devoted time to social duties and was a member of the following: Civitan Club (Governor); Citizens Guild of Washington's Boyhood Home; University Club, New York City; New York Railroad Club; Southern Maryland Society; Manhattan Club; Pequot Yacht Club; Old Colony Club; Brooklawn Country Club; Fairfield County Hunt Club; Longshore Beach and Country Club; Alumni Association of Stevens Institute of Technology; and Delta Tau Delta Fraternity.

Mr. Hill died in New York City on October 18, 1936. He is survived by his widow, Florence (Acheson) Hill; a sister, Mary (Hill) Mills; and two children by a former marriage, Nicholas Snowden Hill, III, and Isabelle (Hill) Guthrie.

Mr. Hill was elected a Member of the American Society of Civil Engineers on October 10, 1916.

ROBERT BRUCE HOADLEY, JR., M. Am. Soc. C. E.[1]

DIED DECEMBER 25, 1937

Robert Bruce Hoadley, Jr., was born at Camanche, Iowa, on March 22, 1879, the son of Robert B. Hoadley and Harriet (Rood) Hoadley. The family removed from Iowa to Binghamton, N. Y., where he attended the public schools. After his graduation from the Binghamton Central High School, he entered Union College, at Schenectady, N. Y., from which he was graduated, in 1902, with the degree of Bachelor of Engineering.

---

[1] Memoir prepared by John A. Giles, Esq., Binghamton, N. Y.

During his summer vacation, previous to graduation, he was employed by the United States Geological Survey. In 1902, he entered the service of the Western Maryland Railway Company as Topographer, and continued as Resident Engineer and Locating Engineer on its lines in West Virginia and Pennsylvania until 1907.

In the first six months of 1907, Mr. Hoadley was employed by the Western Pacific Railway Company in charge of its Drafting Office on 400 miles of new construction in Nevada. In the latter part of the same year he was engaged by the Ely (Nev.) Townsite Company to take charge of a steam-turbine power development.

Returning to his home in Binghamton in 1908, he entered the service of the New York State Highway Department and was connected with this Department until 1917 as Assistant Engineer and First Assistant Engineer in charge of surveys, design, and construction on highways in Broome and Delaware Counties, New York.

Leaving the New York State service, after nine years with its Highway Department, Mr. Hoadley entered private practice, with an office in Binghamton, and from 1919 until his death, had continued under the partnership of Hoadley and Giles.

During his twenty years as a practicing engineer, his endeavors resulted in the design and successful construction and operation of many water and sewerage projects in the development of West Endicott and Johnson City for the Endicott Johnson Corporation, in neighboring villages in the territory of the Binghamton District, in adjacent counties of Pennsylvania, in subdivision work and in the planning of its necessary utilities in New York and Florida. He was also employed by the J. G. White Engineering Corporation for a period of one year, in 1927–1928, in a comprehensive sewerage and sewage disposal design for Bogota, the capital of Colombia.

His endeavors were not entirely confined to his private interests, for he served as a member of the City Planning Commission, Consultant for the Traffic Committee, and as a member of the Committee for the Rehabilitation of the Water-Works, in his own community—the City of Binghamton—for a period of several years.

His career was notable because of his interest in the younger members of the profession and his helpfulness in promoting their progress and success, his fairness and ethical dealings in his engineering contact with others, and a rare sense of humor and human understanding which endeared him to his many associates.

In 1909, Mr. Hoadley was married to Florence C. Jones, of Burlington, Vt., who died in 1929.

He was killed on Christmas Day, 1937, in an automobile accident in Jacksonville, Fla., where he had gone for a holiday visit to his daughter, Mrs.

Richard (Jane Hoadley) VanKleeck, who with two grand-children, and two sisters, Mrs. Agnes Tay, and Mrs. Eugenia Comstock, survives him.

Mr. Hoadley was elected a Member of the American Society of Civil Engineers on July 11, 1921.

RICHARD FREDERICK HOFFMARK, M. Am. Soc. C. E.[1]

Died November 29, 1937

Richard Frederick Hoffmark, the son of Simon Hoffmark and Marie (Baumgarten) Hoffmark, was born in Bremen, Germany, on April 7, 1882. Brought to America at an early age by his parents, who chose to settle in the Middle West, Mr. Hoffmark attended Purdue University, at Lafayette, Ind., where he was active in athletics, particularly football, and was graduated with the degree of Bachelor of Science in Civil Engineering in June, 1906.

On June 18, 1906, immediately after his graduation, Mr. Hoffmark was appointed a Rodman in the service of the Isthmian Canal Commission. He arrived in Empire, Canal Zone, and reported for duty on June 25, 1906. On October 1, 1906, he was appointed Levelman. He was transferred from the Culebra Division of the Isthmian Canal Commission to the Panama Railroad on June 28, 1907, and was promoted to Levelman II, on July 1, 1907, to Instrumentman on February 1, 1908, and was again promoted on November 1, 1908. He resigned from the service of the Panama Railroad on June 6, 1910. During this period Mr. Hoffmark received the groundwork of varied construction experience that was to stand him in such good stead in later years, for he also held positions as Foreman in the Bridge and Building Department and Supervisor of Construction in the Roadmaster Department of the Panama Railroad, and thus early gained wide, practical experience.

It was at this time that Mr. Hoffmark established a friendship that was to be lifelong, with Ralph Budd, M. Am. Soc. C. E., who was then Chief Engineer of the Panama Railroad.

In May, 1910, he returned to the United States to accept a position as Transitman and Resident Engineer on the construction of the Oregon Trunk Railroad in Central Oregon, under Mr. Budd, who was then Chief Engineer of the Oregon Trunk Railroad Company. Mr. Hoffmark worked directly under the late J. C. Baxter, M. Am. Soc. C. E., who was then Mr. Budd's Assistant.

On the completion of this assignment, Mr. Hoffmark, on June 28, 1911, was married to Helen Slifer, daughter of the late Hiram J. Slifer, M. Am. Soc. C. E. (who was formerly General Manager of the Panama Railroad, and later a Lieutenant Colonel with the 21st Engineers, United States Army).

Mr. Hoffmark left the United States immediately after his marriage to accept an appointment as District Superintendent of the Alaska Road

---

[1] Memoir prepared by Natt McDougall, Esq., Portland, Ore.

Commission, for the Nome District, under the direct charge of Lieutenant, later, Colonel, G. E. Edgerton, Corps of Engineers, U. S. Army, M. Am. Soc. C. E. Mr. Hoffmark had charge of all general road and bridge building for the District, and the maintenance of the same. This included locating and staking trails in winter, for the use of dog teams, chiefly in carrying the mail, those on land being constructed with some effort for permanency. His work with the Alaska Road Commission was very valuable and was recognized by at least one promotion during his short period of service.

In November, 1912, Mr. Hoffmark made a connection that was to last for nearly twenty years, for at that time he joined the staff of Guthrie, McDougall and Company as a Field Superintendent in charge of the construction of railroads, tunnels, bridges, and irrigation canals.

In July, 1916, Mr. Hoffmark was called to the Western Office of the Company, which had become A. Guthrie and Company, Incorporated, to assume the position of Western General Superintendent, in Portland, Ore. The firm operated as contractors on all types of heavy construction projects, and Mr. Hoffmark's field of activity became the Far West in general and the Pacific Northwest in particular. His work was as broad in scope as the territory which he covered. For the next sixteen years he was the Contracting Executive responsible for the preparation of proposals and the construction of millions of dollars worth of all kinds of projects, including railroads, highways, tunnels, bridges, dams, irrigation canals, and buildings and structures of varied types and kinds, all of which contributed their share to his ever-broadening practical knowledge of construction in all its phases.

Notable among the projects that were constructed under Mr. Hoffmark's active direction during this period were: The West Okanagon Valley Irrigation project, in the State of Washington; a 4-mile section of the Hetch Hetchy water supply tunnels, in California; the Cushman Dam and Power-House for the City of Tacoma, Wash.; Echo Dam, near Ogden, Utah; the Leaburg hydro-electric project, in Oregon; several large paper mills; and many lesser construction jobs.

In November, 1925, A. Guthrie and Company, Incorporated, was awarded the contract for the construction of the new 8-mile Cascade Tunnel for the Great Northern Railway Company, 90 miles east of Seattle, Wash., with the provision that the tunnel was to be completed and ready for operation in three years. This was accepted as a challenge to the spirit of the force that was to do the work, and to "Dick" Hoffmark fell the vital task of leadership in the field. He moved directly to the site of operations and remained on the ground almost constantly during the organization period, which lasted more than a year, planning and directing the work which had to be done on a high-speed schedule never before equalled or even approached in the field of tunnel driving. New and untried methods were devised and put into operation, modern equipment which has since become standard, was developed for the work, and for three years almost to the day the crews kept up their incessant rounds of drilling, blasting, and mucking, imbued with that spirit of creative workmanship and forceful action so well exemplified by the man under whose active direction they were working.

The Cascade Tunnel being successfully completed in record time, Mr. Hoffmark was elected a Vice-President of A. Guthrie and Company, Incorporated, and, in 1928, he journeyed to the far-off Peruvian Andes to direct the work of his Company's forces on a large tunnel contract for the Cerro de Pasco Copper Corporation. This work also included a sizable railroad location project, and due to his varied experience, Mr. Hoffmark was exceptionally well fitted to handle the assignment.

The construction of the 100-mile extension of the Great Northern Railway, from Klamath Falls, Ore., to Bieber, Calif., was the last job handled by Mr. Hoffmark for A. Guthrie and Company, Incorporated, and upon its completion in the spring of 1932 he resigned his position with this firm and accepted an appointment as Assistant to the President of Carey, Baxter and Kennedy, of New York, N. Y. He had direct charge of the building of the Outside Bowl, on Long Island, for the Madison Square Garden Corporation.

In the spring of 1933 he was made General Manager for Woods Brothers Construction Company, of Lincoln, Nebr., and had general charge of its contracts, which consisted chiefly of the construction of pile dikes, revetments, dredging, and similar work on the Missouri and Mississippi Rivers. He held this position until his death at his home in Lincoln, on November 29, 1937, which was due to an illness of several months' duration.

As Engineer in the fullest sense of the word, " Dick " Hoffmark was noted as an unusually able student of construction in all its manifold phases. Endowed with rare analytical ability, he supplemented this with a knack for practicality in his work that was founded on a broad understanding of sound engineering fundamentals and wide experience. His love for his work and his fellow men placed him high in the esteem of those who knew and worked with him, and his passing is a source of regret to construction men of both high and low degree throughout the United States.

At the time of his death, he was a member of the Nebraska Engineering Society and the Engineers' Club, of Lincoln.

He is survived by his widow and one daughter, Helen Jessie Hoffmark.

Mr. Hoffmark was elected an Associate Member of the American Society of Civil Engineers on March 5, 1912, and a Member on December 16, 1929.

THOMAS HERBERT JACKSON, M. Am. Soc. C. E.[1]

Died April 8, 1937

Thomas Herbert Jackson, the son of Noah W. and Pauline (Adams) Jackson, was born at Westmeath, Ont., Canada, on January 18, 1874. He was descended from early Colonial stock, his forebears having settled in the Colonies prior to the Revolution. He was brought to the United States by his parents in 1880 and spent his boyhood on a farm near Montague, Mich., where he experienced early in life the physical toil attendant to farming. He attended Grammar School and High School, in Muskegon, Mich. When the local Congressman consulted the Principal of the High School concerning an appointment to the United States Military Academy, at West Point, N. Y., the Principal gave it as his opinion that young Jackson had the best mind in the school. He was selected for the appointment and entered the Military Academy as a Cadet on June 15, 1895. He was graduated Number Six in his Class and appointed a Second Lieutenant of Engineers on February 15, 1899.

---

[1] Memoir prepared under the direction of Major General E. M. Markham, Chf. of Engrs., U. S. Army, M. Am. Soc. C. E.

Lieutenant Jackson's first assignment was as Assistant to the District Engineer, at Portland, Me. He completed the course at the Engineer School of Application, at Willets Point, N. Y., in 1902. In 1903, he went on foreign service in the Philippine Islands, where he was on duty as Engineer Officer, Department of the Visayas, at Iloilo, and performed duties pertinent to the establishment of the Military Post of Fort William McKinley, until August, 1905.

Returning to the United States, Lieutenant Jackson was stationed with the 2d Battalion of Engineers at Fort Leavenworth, Kansas, and having been promoted to the rank of Captain, he was appointed District Engineer of the Third San Francisco (Calif.) District, in 1907. During his 4-yr tour in San Francisco he formulated the plans for the Sacramento River Flood Control Project which is now (1937) nearing completion, at a cost of $50 000 000. The original plan for this project is still referred to as the "Jackson Plan." It provided for the utilization of a system of by-passes in addition to levees for the control of floods. In this respect, it is a prototype of the plan later adopted for control of floods on the Mississippi River. Subsequently, for the period 1911 to 1917, Major Jackson was assigned as District Engineer at Dallas, Tex., and at Wheeling, W. Va. He was promoted to the rank of Major in 1912.

Upon the entry of the United States into the World War, Major Jackson was assigned as Instructor of the Citizens' Training Camp, at Madison Barracks, New York. In August, 1917, as a Colonel of Engineers, he proceeded to France and, in March, 1918, was assigned as Section Engineer of the Advance Section, Services of Supply. After holding various important positions in the Services of Supply, he was assigned on January 6, 1919 as Engineer Supply Officer of the American Expeditionary Forces, at Paris, France, and, in July, was made Chief Engineer Officer of the American Expeditionary Forces. Colonel Jackson was awarded both the Purple Heart and the Distinguished Service Medal for exceptionally meritorious and distinguished services in these various positions. He was also an Officer of the Legion of Honor, France; Commander, Order of Leopold II, Belgium; and had received the Polish Order of Valiant.

Upon his return to the United States, he returned to the grade of Lieutenant Colonel and after a tour on supply duty in the Office of the Chief of Engineers, at Washington, D. C., he proceeded to Camp Grant, Illinois, where he demobilized the 318th Engineers. In 1921, after his promotion to the grade of Colonel, he was assigned as Instructor of the National Guard at Kansas City, Mo., but remained on this duty only a few months before proceeding to San Francisco as Corps Area Engineer. In 1926, Colonel Jackson was assigned as Division Engineer of the Pacific Division, which assignment was followed by a short tour in New Orleans, La., as Division Engineer of the Gulf Division. In 1928, he was appointed President of the Mississippi River Commission and Division Engineer of the Western Division, of the Engineer Department. He had the distinction of being the first Army Officer to be so appointed under the new plan of organization established in 1928, the appointment carrying with it the rank of Brigadier General.

It was in the position of President of the Mississippi River Commission that General Jackson rendered his most outstanding service to his country. He personally established the organization for doing the work on the Mississippi River provided for in the $300 000 000 program approved by Congress in May, 1928. About one-half this program was completed during his 4-yr tour as head of the Commission.

Upon completion of his assignment on the Mississippi, he was appointed Division Engineer, South Atlantic Division, which post he held for two years. General Jackson returned to San Francisco, in 1934, as Division Engineer, South Pacific Division, and President of the California Débris Commission. This was his third detail on the Débris Commission, and he became recognized as a high authority on all phases of hydraulic gold mining. He was retired on March 31, 1937, on account of disability incurred in line of duty, and died on April 8, 1937, at Tsingtao, China, while en route around the world on the S. S. *Reliance.*

He was married on August 24, 1912, at St. Louis, Mo., to Maude Edgar, who survives him.

General Jackson will long be remembered by the Junior Officers of the Corps of Engineers as one who took unfailing interest in their professional development. He was never too busy to spare the time to instruct a junior officer in some phase of his work, which would prepare him for responsible positions in the future.

In view of his broad experience and keen technical mind, General Jackson was regarded in the Corps of Engineers as its outstanding authority on flood control and organization matters.

His citation for the Distinguished Service Medal was as follows:

> "For exceptionally meritorious and distinguished services. As a member of the Division of Construction and Forestry, he displayed untiring energy and marked ability in the performance of his important duties. His stupendous task was fraught with numerous difficulties, which he overcame with noteworthy success, rendering services of signal worth to the American Expeditionary Forces."

In writing of his career, General Malin Craig, Chief of Staff, U. S. Army, concluded:

> "General Jackson was a loyal, able, and zealous officer, strong in convictions and forceful in action. He possessed splendid engineering and or-

ganizing ability, keen initiative, sound judgment, and the capacity for hard work. During his military career of more than forty-one years, he was outstanding in his efficiency and rendered invaluable service to his country during the trying times of war as well as in peace, and was signally honored in his profession. The many commendations of his superiors attest to the esteem in which he was held by his associates. His death is deeply regretted."

General Jackson was elected a Member of the American Society of Civil Engineers on July 15, 1929.

CHRISTIAN PETER JENSEN, M. Am. Soc. C. E.[1]

DIED MAY 5, 1937

Christian Peter Jensen was born in Summerville, Calif., on November 9, 1873. His parents, Martin and Adelheid (Jorgensen) Jensen, came to America from Denmark in 1870, going first to Ohio and, later, to California. They were among the first settlers of Central Colony, in Fresno County, and it was there that Mr. Jensen attended the public schools. After graduation from High School, he entered the Van der Naillen School of Engineering, in Oakland, Calif., from which he was graduated in 1895.

After a short engagement with the Sanborn Map Company, of San Francisco, Calif., Mr. Jensen returned to Fresno and entered the firm of I. Teilman, M. Am. Soc. C. E., Civil Engineer. Later, the two engineers became associates under the firm name of Teilman and Jensen, which association continued until 1906.

The practice of civil engineering in Central California at that time was wide and varied in its scope. Of particular interest was the engineering work done in connection with the location and construction of lumber flumes, logging railroads, mountain roads, and irrigation systems. At this period in the history of Fresno and the San Joaquin Valley, lumbering in the Sierra Nevada Mountains, at the eastern edge of the Valley, was much more of a major industry than it is at the present time. The product of the smaller mountain saw-mills was hauled to the Valley towns, about sixty miles, over rough, dusty, mountain roads, in great wagons drawn by 12 to 16-mule teams, but the larger mills found it economical to float their lumber to the Valley by swiftly flowing water in **V**-shaped timber flumes.

In the mountains these flumes clung to the sides of the canyons, crossing ravines and gullies on high trestles, and continuing on descending grade on trestles until they reached their destination in the planing mills and lumber yards of the San Joaquin Valley towns of Fresno, Madera, Clovis, and Sanger. The location, design, and construction of these flumes called for high engineering skill and judgment. In this period, also, there were still being constructed the large irrigation systems which transformed the dry plains of the San Joaquin Valley to the present fertile fields and vineyards.

---

[1] Memoir prepared by a Committee of the San Francisco Section, consisting of Henry D. Dewell and Harold K. Fox, Members, Am. Soc. C. E.

Mr. Jensen had an important part in the engineering features of this early industrial and agricultural development of Fresno County and also of adjacent counties. In 1900, he was Assistant Engineer on the location survey and the construction of the 54-mile lumber flume for the Madera Sugar Pine Company, in Madera County; from 1901 to 1904, he was Chief Engineer of this Company, engaged in the location and construction of logging railroads and related structures; from 1902 to 1917, he was Consulting Engineer for the Madera Canal and Irrigation Company in investigations pertaining to duty of water, legal work, and construction of canals and siphons; from 1904 to 1909, he was Chief Engineer of the Settlers Branch Canal, Kings County, where he located and constructed 50 miles of canal and related structures, including a large weir across the Kings River; from 1910 to 1919, he was Chief Engineer of Reclamation District No. 1 604 on designs and construction of levees on the San Joaquin River; he was also, during this period, Chief Engineer for J. C. Forkner, of Fresno, in the subdivision and irrigation of 6 000 acres.

From 1909 to 1913, Mr. Jensen was City Engineer of Fresno; from 1912 to 1914, Consulting Engineer for the City of Bakersfield, Calif., and Engineer for the City of Dinuba, Calif., on the design and construction of sewers and sewage disposal systems; from 1912 to 1919, he was City Engineer of Clovis; from 1913 to 1917, City Engineer of Sanger; from 1913 to 1919, City Engineer of Reedley, Calif.; from 1913 to 1914, he also served as Engineer on the design and construction of water-works for the Town of Strathmore, Calif.; from 1913 to 1919, Chief Engineer of the Fresno Traction Company; and from 1915 to 1919, City Engineer for the Town of Fowler.

From May, 1917, to January, 1919, Mr. Jensen was associated with his brother, the late Andrew Martin Jensen,[2] M. Am. Soc. C. E., and Mr. J. A. Ross, under the firm name of Jensen, Jensen, and Ross, Civil Engineers.

In 1919 Mr. Jensen became County Surveyor of Fresno County and Chief Engineer of the Fresno County Highways, for the construction of highways under a $4 800 000 bond issue. Mr. Jensen developed the Jensenite Paving Process, which was widely used, and eliminated the payment of royalties to private paving concerns, thus saving the County thousands of dollars. The satisfactory service which Mr. Jensen rendered as County Surveyor is evidenced by the fact that he was returned to that office every four years and occupied the office until his death.

In January, 1896, Mr. Jensen was married to Isabelle Malcolm Baird, of Fresno. The two children of this marriage were Katharine and Donald. Six years later, in 1902, his wife passed away. In August, 1909, he was married to Bertha Franklin Coleman, at San José, Calif. The two children of this marriage were Elizabeth and Mary. He is survived by his widow, Mrs. Bertha Franklin Jensen, and by three of his children, Donald, Elizabeth, and Mary.

---

[2] See Memoir, *Transactions*, Am. Soc. C. E., Vol. 96 (1932), p. 1504.

Mr. Jensen was active both in professional and civic affairs. He was Past-President of the Engineers' Club of Fresno, of the Fresno Commercial Club, and of the Fresno Exchange Club. He was also an active member of the State Chamber of Commerce. He was Past Master of Los Palmas Lodge, No. 366, of the Free and Accepted Order of Masons; Past Commander of Fresno Commandery No. 29, Knights Templar; Past High Priest of Fresno Chapter No. 69, of the Royal Arch Masons; Past Patron of Raisina Chapter of the Eastern Star, and also of the Royal Order of Amaranth; and Past-President of the Fresno Shrine Club.

Mr. Jensen was elected an Associate Member of the American Society of Civil Engineers on January 31, 1911, and a Member on October 15, 1919.

JOSIAH RAYMOND JOHNSTON, M. Am. Soc. C. E.[1]

Died April 13, 1938

Josiah Raymond Johnston was born on February 13, 1890, in Ottawa, Kans., the son of Josiah K. and Nancy Jane Johnston. His education was begun in the Grade School, at Ottawa, and was continued in the Grade School and High School at Greenfield, Iowa. He was graduated, in 1913, from Iowa State College, at Ames, Iowa, with a degree of Bachelor of Science in Civil Engineering.

Mr. Johnston began his professional work in 1913 as Engineer on drainage in Murray County, Minnesota. Later, he was elected County Surveyor of Murray County, which office he held when the United States entered the World War in 1917.

In May, 1917, Mr. Johnston enrolled in the first Officers' Training Camp, at Fort Snelling, Minnesota, and in July he was commissioned as First Lieutenant, in the Corps of Engineers, United States Army. In October, 1918, he was promoted to the grade of Captain. He commanded Headquarters Company, 313th Engineers, 88th Division, in training at Camp Dodge, Iowa, and, later, in service with the 88th Division in France. He was honorably discharged from the Army as a Captain in August, 1919, his entire war service having been with the 313th Engineers.

From August, 1919, to April, 1923, he was engaged first as a Drainage Engineer in private practice in Southern Minnesota and, later, as an Engineer and as a Consulting Engineer on drainage, paving, and sewer work, with headquarters at Slayton, Minn.

In April, 1923, he accepted the position of Assistant Superintendent, and in December, 1936, was promoted to that of Superintendent, of the Bureau of Construction and Repair, Department of Public Works, at St. Paul, Minn. Except for the period from June, 1934, to February, 1936, Mr. Johnston's service with the Department of Public Works was continuous to the time of his death. From June, 1934, to February, 1936, he served as an Engineer Special Agent for the Division of Investigation, Federal Emergency Administration of Public Works. This work included engineering investigations of construction projects in Minnesota, North Dakota, South Dakota, Nebraska, Washington, Oregon, Idaho, and Montana. He resigned from the Public Works Administration in February, 1936, to return to city service in St. Paul.

---

[1] Memoir prepared by William N. Carey and George M. Shepard, Members, Am. Soc. C. E., and George M. Garen, Assoc. M. Am. Soc. C. E.

During the thirteen and one-half years of Mr. Johnston's service with the Department of Public Works in the City of St. Paul, his work embraced many phases of municipal construction. He personally directed the construction of several difficult sewer and paving projects done by city forces. He also supervised the engineering inspection of contract work, sewers, pavements, street widening, grading, etc., totaling more than $10 000 000 in value. For several years, in addition to his other duties, he was responsible for the maintenance of all graded but unpaved streets and alleys in the city—about 450 miles in all. In connection with this work he became a leader in the development of low cost, asphaltic street-surfacing methods ranging from simple, road-oil treatments to various types of low cost, secondary type, asphaltic pavements. To him, more than to any one else, should be given the credit for transforming with little money, the unpaved streets and alleys of St. Paul from a condition where dust, ruts, holes, and mud all too often prevailed to one closely approaching the all-year-round smoothness and usefulness of permanently paved streets.

Mr. Johnston possessed, to a most unusual degree, the faculty for making friends. He was affectionately known to all by his Army nickname, "Josie." He was never too busy to listen to the troubles of others and help them if possible. People of all walks of life from State and City officials to the lowliest laborer who came in contact with him felt and quickly appreciated the real warmth and sincerity of his friendliness. He seemed, too, to have some secret password directly into the affections of little children and dogs. He enjoyed sports—hunting and golf particularly—and the society of men outdoors.

For many years before his death Mr. Johnston put much of his time and energy into the activities of the engineering organizations of his City and State. He held, in succession, all the offices of the St. Paul Engineers' Society from Secretary to President. For several years he was continuously a Director of the Minnesota Federation of Architectural and Engineering Societies and Secretary-Treasurer of that organization, which office he held at the time of his death. He was a member of the Merriam Park Presbyterian Church, of St. Paul, and a Thirty-Second Degree Mason. His college fraternity was Pi Kappa Alpha. He was an active member of the American Legion, a Past Commander of Highland Park Post of St. Paul, and was much interested in American Legion welfare activities.

On June 29, 1918, he was married to Louise Whitney, of Slayton, who survives him. They had no children.

Mr. Johnston was elected a Member of the American Society of Civil Engineers on April 12, 1926.

WINFRED MILLER KALLASCH, M. Am. Soc. C. E.[1]

DIED JUNE 8, 1937

Winfred Miller Kallasch, better known as "Bill" to his host of friends, was born on March 27, 1877, on a farm near Perry, Ill. His father, Edward Kallasch, lived on a farm, but was a cabinet maker by trade.

Winfred Kallasch was graduated, in 1902, from the University of Nebraska, at Lincoln, Nebr., with the degree of Civil Engineer. His first work after leaving the University was with the Chicago Great Western Railroad Company as Masonry Inspector of concrete arches and abutments. This work lasted only a short time, and in October, 1902, he went with the Illinois Central Railroad Company, in the Bridge and Building Department, as Masonry Inspector, being promoted later to the position of Resident Engineer on the construction of a 280-ft draw-bridge over the Yazoo River, at Yazoo, Miss. While with the Illinois Central, he designed and built a temporary lift-bridge for maintenance of traffic during construction, and was then made Assistant Resident Engineer on the Tennessee River Bridge. Following this engagement he was transferred to Memphis, Tenn., as Assistant Engineer in general charge of the construction of concrete arches, abutments, and bridges on Southern Lines. From February to November, 1907, he was with the Construction Department of the Illinois Central System as Resident Engineer on double-track at Memphis, this work including bridges, viaducts, and the re-arrangements of streets and sewers.

In November, 1907, Mr. Kallasch left the Illinois Central Railroad Company for a connection with the Leonard-Martin Construction Company, in the capacity of Superintendent of Construction of bridges, viaducts, and warehouses. For a short period, from December, 1908, to June, 1909, he was with the Missouri Pacific Railway Company as Resident Engineer on the reconstruction of the Arkansas River Bridge, near Helena, Ark., sinking two large piers by the pneumatic process and transferring the 300-ft steel span across the river.

In June, 1909, he returned to the Leonard Construction Company as General Superintendent of Construction on reinforced concrete for the Union Passenger Station, at Gary, Ind.; grade-crossing track elevation for the Illinois Central Railroad Company, at Chicago, Ill.; the Mulnomah Hotel, at Portland, Ore.; the plant of the Corn Products Refining Company, at Pekin, Ill.; the "Soo" Line Freight Terminal, at Chicago, consisting of a yard on an elevated reinforced concrete structure covering eleven city blocks, as well as buildings and other facilities for the rapid handling and storage of freight; and in charge of the construction and field engineering on a zinc ore-reducing and sulfuric acid plant for the Mineral Point Zinc Company, at Wheeling, W. Va.

---

[1] Memoir prepared by H. B. Bushnell, Vice-Pres., Western-Austin Co., Aurora, Ill.

In July, 1914, Mr. Kallasch left the Leonard Construction Company to accept the position of Engineer and Executive Officer in charge of operations for the Illinois Hydraulic Stone and Construction Company, at Elgin, Ill. He had been interested in this Company since 1906, but until 1914 had devoted very little of his time to its operation. While with this Company he built concrete roads, municipal improvements, factories, buildings, and warehouses. From May, 1917, to April, 1918, he returned again to the Leonard Construction Company, in Chicago, as General Field Superintendent on the Donnelley Building and the Chicago District Station of the Sinclair Refining Company; the plant of the Inter-Ocean Refining Company, at McCook, Ill., and the Federal Rubber Company's plant, at Milwaukee, Wis. In April, 1918, he was appointed General Superintendent and Manager of Work on Explosives Plant "C", for the United States Government, at Nitro, W. Va., this plant costing approximately $7 000 000. After the completion of this war work, Mr. Kallasch remained with the Leonard Construction Company as General Field Superintendent in charge of the construction of large industrial plants until 1924, at which time he assumed the duties of Plant Superintendent and Manager of the Crown Electric Company, at St. Charles, Ill. In March, 1925, he returned to the Illinois Hydraulic Stone and Construction Company, at Elgin, as Vice-President, which position he held at the time of his death.

On December 5, 1914, Mr. Kallasch was married to Cleo Frances Burtis, of Hudson, Ill., and is survived by his widow, a brother, Ernest Kallasch, of Tacoma, Wash., a sister, Cora Kallasch, of Centralia, Wash., and a niece, Inez Carr, of Los Angeles, Calif.

He was a splendid engineer and constructor, a hard worker and an exceedingly thorough one. He lived an interesting and useful life, and had an active part in the building of many worth while projects.

Mr. Kallasch was elected an Associate Member of the American Society of Civil Engineers on May 6, 1914, and a Member on March 11, 1919.

FRANCIS HOWE KENDALL, M. Am. Soc. C. E.[1]

Died October 7, 1937

Born in Belmont, Mass., on August 23, 1869, Francis Howe Kendall retained his residence in that town throughout his life. His parents were Josiah Shattuck and Martha Helen (Wellington) Kendall, both of whom were descended from families that were among the first to settle in what was originally known as "Pequossette Plantation," later included in the Towns of Belmont and Watertown.

Josiah Kendall was a farmer, and, as might be expected from one of his ancestry, he had a high sense of personal obligation to his home town, and served it for many years in various capacities, such as Assessor, member of the School Committee, and Selectman. This feeling of duty to the community, which New Englanders like to consider as typical of the best of the founders, was an especially marked characteristic of Francis Kendall, who devoted practically all his mature life to public service, especially to the County of Middlesex, by which he was employed, and to the Town of Belmont, in which he lived.

---

[1] Memoir prepared by Charles W. Sherman and Harry B. Burley, Members, Am. Soc. C. E.

Francis Kendall attended the public schools at Belmont. After graduation from the High School, in 1885, he decided to study Civil Engineering, and entered the Case School of Applied Science, at Cleveland, Ohio, where he remained for three years. In 1888, he entered the junior class at Massachusetts Institute of Technology, at Boston, Mass., and was graduated with the Class of 1890. During the following year he was Assistant to the Professor of Railroad Engineering at the Institute.

From June, 1891, to November, 1892, Mr. Kendall was Assistant Engineer with the Cleveland, Cincinnati, Chicago and St. Louis Railway Company, in Ohio. In 1892, he became Assistant Engineer under the late Charles Mills, then Engineer of Middlesex County, Massachusetts, and upon Mr. Mills' resignation Mr. Kendall succeeded him as County Engineer, on July 1, 1894, and held this position until his death.

As County Engineer, Mr. Kendall's duties were primarily to advise the County Commissioners on all technical matters relating to roads, dams, bridges, and buildings. In many cases the construction or reconstruction was by joint action of county, State, and town, and proper co-ordination of action was of the greatest importance. The highway system within Middlesex County was developed greatly during his term of service, and a large part of the improvement was accomplished as a result of his wise counsel, patience, and tact, as well as sound engineering judgment. Dams within a county are under the supervision of the County Commissioners, and under Mr. Kendall's advice the Commissioners required repairs and changes in such structures from time to time to effect a greater degree of safety. No such structure under his supervision ever failed with resulting loss of life. Bridges were rebuilt, repaired, or replaced, to provide adequate strength and, at the same time, to secure a pleasing appearance and avoid unreasonable expense. Mr. Kendall was not a bridge designer, but his advice and assistance resulted in obtaining structures which bear evidence of his good judgment. Plans of location, approaches, grading, sewers, and drains for county buildings, such as court houses, correctional institutions, hospitals, etc., were prepared by him and utilized in the construction, alteration, and repairs of such buildings.

Mr. Kendall served the County Commissioners as Secretary as well as Engineer, and, finding that a considerable knowledge of law was essential to his work, he took a correspondence course in law. This, and the experience in such legal matters as he acquired in the course of his duties, resulted in his becoming, as some lawyers have stated, probably the best posted man in the State on legal affairs relating to counties, although he never applied for admission to the Bar. In 1922, under legislative authority, he prepared a compilation of laws relating to counties in Massachusetts. His duties as

Secretary involved the preparation of estimates of receipts and expenditures submitted annually to the Legislature for the county budget; the preparation of bills for legislative action; the submission each year to the Clerk of Courts of a detailed order assessing the expenditures of maintaining the Middlesex County Sanitarium upon the communities making up the hospital district; and the preparation of legal briefs and returns relating to county highways and bridges.

The record of Mr. Kendall's service to the Town of Belmont is an impressive one, the more so because most of it was rendered as a civic duty, and without financial recompense. He served twelve years as a member of the Board of Water Commissioners, and ten years as Selectman. For years, he was a member of the "Warrant Committee"—the town's budget committee—and he also served on ten or twelve special committees. There was no citizen of the town whose opinion and judgment carried greater weight with the voters.

Besides his direct service to the town as a municipality, he gave much to its development as a "town of homes." He was one of a group that formed a real estate trust and developed an area with such restrictions and on such a plan that it would benefit the community, without regard to the question of gains to the investors. Later developments have been made along similar lines, to the great advantage of the town. Mr. Kendall served the Belmont Savings Bank as Trustee for more than thirty years, having been its President for fifteen years. He was also a Director of the Waverley Co-operative Bank.

Modest and somewhat retiring by nature, Mr. Kendall was not a man to push himself into public notice, or to claim the credit for accomplishments which resulted in large measure from his unselfish work. No monumental structures can be pointed out as examples of his skill and ability as an engineer; no great reform or notable achievement as a public official can be claimed as essentially his. His life was made up of a multitude of comparatively small accomplishments, the aggregate of which constitutes an inspiring example of what a man can do and be in his own community, through years of simple, upright, honorable living.

Mr. Kendall was married, in 1900, to Lilly Miller, who survives him.

He was a Member of the Boston Society of Civil Engineers, and the Massachusetts Highway Association.

Mr. Kendall was elected a Member of the American Society of Civil Engineers on October 1, 1926.

THOMAS HENRY KING, M. Am. Soc. C. E.[1]

Died November 8, 1933

Thomas Henry King was born in Baltimore, Md., on July 29, 1877, the son of Thomas Harmon King and Ann (Booz) King. His early education was received in the public schools and in Deichman's Preparatory School of Baltimore. In 1896, he entered Johns Hopkins University, at Baltimore, where he completed two years of study as a Special Student in Electrical Engineering.

---

[1] Memoir prepared by Irving C. Hess, Assoc. M. Am. Soc. C. E.

In 1898, Mr. King entered the employ of a general contractor in Baltimore and served, successively, as Draftsman, Estimator, and Office Engineer until 1903, when he went into business for himself as a General Contractor in the same city. From 1909 to 1913, Mr. King was a member of the engineering firm of King and Barnes, of Baltimore, engaged in engineering design and superintendence of construction.

In 1913, Mr. King moved to San Diego, Calif., and for a year served as Chief Draftsman for D. L. Bissell, City Engineer for the Towns of La Mesa, El Cajon, and East San Diego, Calif. He next entered the employ of the City of San Diego as a Draftsman in the City Engineer's Office and worked on reinforced concrete design, etc., for a period of about one year. In 1915, he was employed as an Engineer for H. M. Byllesby and Company, engaged in valuation of the San Diego Consolidated Gas and Electric Company's properties, in San Diego.

Visualizing the future importance of water supply in Southern California, Mr. King decided, in 1916, to specialize in water supply and distribution, particularly in San Diego County. In 1916, he entered the service of the Volcan Land and Water Company, and from that time until his death he was prominently identified with water supply and distribution in San Diego County. He served, successively, as Chief Draftsman, Chief Office Engineer, and Designing Engineer for the Volcan Land and Water Company, and, when the San Dieguito Mutual Water Company was formed as an outgrowth of the Volcan Company, he served as Chief Office Engineer and Designer until 1919 for that Company. During this period the Lake Hodges System was constructed which included Lake Hodges Dam, an Eastwood multiple-arch dam, 133 ft high and 750 ft long; the San Dieguito Dam, also an Eastwood multiple-arch dam, 50 ft in height and 700 ft in length; 4½ miles of concrete conduit connecting Lake Hodges and San Dieguito Reservoirs; and about 10 miles of main distribution lines. This conduit had many unique features of design including a 42-in. reinforced concrete siphon and a pre-cast concrete trestle, both designed by Mr. King. At the time it was built, the precast concrete trestle attracted widespread attention.

From 1919 to 1922 he served as Chief Engineer of the Ed Fletcher Company, of San Diego, and in that capacity he was Engineer in charge of the Volcan Land and Water Company, as well as having occasional engineering duties in connection with the San Dieguito Mutual Water Company and the Cuyamaca Water Company. As Engineer for the Volcan Land and Water Company, he had charge of certain water supply studies covering practically all of San Diego County. It was during his association with the Cuyamaca Water Company that Murray Dam, an Eastwood multiple-arch dam, 112 ft high and 900 ft long, was constructed for the Cuyamaca Water Company.

From 1922, when the Volcan Water Company was dissolved, until the time of his death, Mr. King was engaged in the private practice of engineering, specializing in water supply and irrigation. However, he also designed and constructed, from 1927 to 1929, more than $2 000 000 worth of public improvement work, including municipal improvement, highways, and sewers. He was associated in some capacity at one time or another with every Irrigation District in San Diego County, and served as Chief Engineer of the San Dieguito Irrigation District, Lakeside Irrigation District, San Ysidro Irrigation District, Ramona Irrigation District, and La Mesa, Lemon Grove and Spring Valley Irrigation District, all located in San Diego County, and the Niland Water District, in Imperial County, California. As Chief Engineer, he designed and constructed the principal works of the following irrigation districts: San Dieguito, Lakeside, Ramona, and La Mesa, Lemon Grove and Spring Valley. The work ranged in cost from a $35 000 bond issue for the Lakeside Irrigation District to a $2 500 000 bond issue for the La Mesa, Lemon Grove and Spring Valley Irrigation District. In 1931, he designed and constructed the first unit of a water development on a 4 000-acre ranch on the Sweetwater River, in San Diego County, owned by Mr. J. W. Sefton.

It is generally recognized that no one person had a more thorough knowledge of the water supply problems in San Diego County than Mr. King. He made water supply investigations on the following streams and their tributaries in San Diego County: San Luis Rey River, San Dieguito River, Santa Ysabel River, Santa Maria Creek, San Diego River, Sweetwater River, Otay Creek, Cottonwood Creek, and the Tia Juana River. The decision of the City of San Diego to build El Capitan Dam instead of a dam at Mission Gorge No. 2 site, on the San Diego River, was due largely to studies of the river made by Mr. King.

His personal interest in public welfare was evidenced by active membership in the Rotary Club of La Mesa, and, later, at San Diego. Fraternally, he was a Mason. His principal hobby was yachting. For five consecutive years he served as a Director of the San Diego Yacht Club. Mr. King was highly esteemed by those who knew him as an upright citizen, a man of high ideals, a true friend, and a competent engineer. In his passing the Engineering Profession loses an honorable member and a strong character.

He was married in Baltimore, on October 30, 1901, to Mary Edna Bedford, who survives him.

Mr. King was elected an Associate Member of the American Society of Civil Engineers on June 19, 1922, and a Member on October 1, 1926.

WILLIAM ALFRED LAMB, M. Am. Soc. C. E.[1]

Died February 9, 1938

William Alfred Lamb was born on December 16, 1881, near Hillside, Colo. His father, Joseph Milton Lamb, born in North Carolina in 1836, was a veteran of the Union Army during the Civil War and was famous as an Indian fighter during early days in Colorado. He achieved particular renown as the slayer, in 1864, of Espinoza, the Mexican bandit, murderer and assassin. He was married to Elizabeth Cantonwine, who went to Colorado with her parents in the days of the ox-team prairie schooner.

---

[1] Memoir prepared by A. H. Tuttle, Esq., Helena, Mont., and C. S. Heidel, M. Am. Soc. C. E., assisted by N. C. Grover, M. Am. Soc. C. E.

William Alfred Lamb attended grade schools at Hillside and was graduated from the Hillside High School in 1897. He entered the Colorado State College, at Fort Collins, Colo., in 1898, and was graduated in 1902 from the Civil and Irrigation Engineering Division with the degree of Bachelor of Science. He taught mathematics at the College for one year after his graduation.

He entered the United States Reclamation Service as Hydrographer, in 1903, at which time it was a branch of the United States Geological Survey. Over a period of six years, Mr. Lamb's work with the Geological Survey was widely diversified, although generally related to water, and took him into many States. In 1909, he was appointed District Engineer for the Helena District of the Water Resources Branch of the U. S. Geological Survey, and, thereafter, Helena, Mont., was his home. His duties as District Engineer included the execution, direction, and supervision of investigations and reports concerning surface water and its utilization, in Montana, North Dakota, and South Dakota. He became a recognized authority on the surface waters of those States and their utilization for all purposes. Although always a Federal official, he was the trusted adviser of the State Engineer and other State officials and citizens.

Mr. Lamb represented the United States in the division, between Canada and the United States, of the international waters of the St. Mary River and the Milk River and their tributaries. His pleasing personality, his unquestioned integrity, and his conscientious attention to official duties won for him the respect and confidence of all interested parties on both sides of the International Boundary. These qualities won him a host of friends throughout the United States and Canada who mourn his untimely passing.

On December 16, 1932, he was appointed by President Herbert Hoover as a Special Representative of the United States in negotiations between the States of Montana and Wyoming relating to a proposed compact for the division of the waters of the Yellowstone River.

A Joint Report by Mr. O. H. Hoover, representing Canada, and Mr. Lamb, representing the United States, on International Forecasting and Apportionment of Waters by the United States and Canada in the St. Mary and the Milk River Drainage Basins, based on the snow surveys on the International Boundary, was presented at the World's Conference on Snow Studies in Edinburgh, Scotland, in 1936.

Among those who feel the loss of Mr. Lamb most keenly are his associates in the office of the U. S. Geological Survey, in Helena. They knew him as a true friend taking a conscientious interest in their welfare.

He was a member of the Helena Lodge of the Benevolent and Protective Order of Elks; of King Solomon's Lodge No. 9, A. F. and A. M.; Past High

Priest of Helena Chapter No. 2, R. A. M.; Past T. I. Master of Helena Council No. 1, R. and S. M.; Past Commander, Helena Commandery No. 2, Knights Templars; a member of Helena Consistory, Thirty-Second Degree Scottish Rite; St. Peter's Conclave No. 8, Red Cross of Constantine; Algeria Shrine; and of the Order of Jesters.

Mr. Lamb was a delegate to the 1927 meeting of the American Legion at Paris, France, and to other national meetings.

He was a Director and Past-President of the Montana Club; a Past-President of the Helena Federal Business Association; and a member of the American Geophysical Union.

In 1918, Mr. Lamb volunteered as a private in the United States Army, and was assigned to the Officers Training Camp, at Fortress Monroe, Virginia. He was honorably discharged from the Army in 1919 with the rank of Captain of Coast Artillery in the Officers Reserve Corps. He maintained his interest in the Reserve Corps and was promoted to the rank of Major on April 4, 1925.

Surviving him are three sisters, Cora Lamb, Mrs. Flora McGlothlin, and Mrs. Martha Adams, and three brothers, C. A. Lamb, J. A. Lamb, and F. R. Lamb.

Mr. Lamb was elected a Junior of the American Society of Civil Engineers on November 5, 1907; an Associate Member on May 3, 1910; and a Member on April 21, 1920.

FRANK PERRY LARMON, M. Am. Soc. C. E.[1]

DIED JUNE 3, 1937

Frank Perry Larmon, the youngest child of John and Laura Frances (King) Larmon, was born on March 2, 1878, at Salem, N. Y. He was of Scotch, English, and French descent.

Hugh Learmouth (the name was later changed to Larmon), the first of the family to come to America, was a native of Falkirk, Scotland. He came to the United States in 1772, and, while yet a young man, was one of the pioneer settlers in Cambridge, N. Y. He married Catherine Laurier, of Dutchess County. Their son, Alexander, and Ruth (Corey) Larmon were the parents of John. Through the King ancestry, Mr. Larmon was a *Mayflower* descendant, tracing direct line to Francis Cook.

John Larmon moved to Cambridge, N. Y., in 1884, and Frank attended the Cambridge Union School, graduating with the Class of 1895. He then entered Rensselaer Polytechnic Institute, at Troy, N. Y., from which he was graduated in 1900 with the degree of Civil Engineer.

Mr. Larmon began his engineering career in September, 1900, as Assistant Engineer of the Hudson River Water Power Company on the reconstruction of Spier Falls Dam, near Glens Falls, N. Y. This work was completed in 1902, and from February of that year, until February 1903, he acted as Assistant Superintendent on the reconstruction of the Street Railway System of Little Rock, Ark.; and afterward as Assistant Superintendent on the construction of conduits and the power plant of the Paxtang Electric Company, of Harrisburg, Pa.

---

[1] Memoir prepared by Alex Larmon, Esq., Charleston, W. Va.

In September, 1903, he was made Assistant City Engineer, of Utica, N. Y., and as such was engaged on the design and construction of general municipal work. From June, 1904, to April, 1907, he was Assistant Engineer for the State of New York on the design and construction of highways and canals and in charge of Barge Canal contracts amounting to more than $2 000 000.

Mr. Larmon entered private practice in April, 1907, his work including the design and construction of a hydro-electric plant for Salem, N. Y., and the investigation and reports on claims against the State and City of New York for damages to riparian rights and property appropriated.

From January, 1909, to June, 1913, he was employed as Engineer for the Lovejoy Company, manufacturers of agricultural implements. Starting in July, 1913, he served as Assistant City Engineer, of Lowell, Mass., in charge of work for the Water Department. He then became Chief Engineer of the Consolidated Water Company, of Utica, on the design and construction of all new work, and the operation of the system. In this capacity, he was engaged in the construction of 5 miles of 24-in. supply main, a 15 000 000-gal distributing reservoir, 15 miles of distribution mains, a stand-pipe (50 ft by 30 ft), and three 24-in. pipe crossings under the Mohawk River and New York State Barge Canal in silt and quicksand.

In 1917, Mr. Larmon went to Cuba as Resident Engineer on the construction of the electric railway and ocean pier in Cienfuegos. Returning to the United States in 1918 he spent the next six years in Omaha, Nebr., as Chief Engineer and Acting Manager of the Metropolitan Utilities District. This work covered the construction and operation of the water, gas, and ice plants—the outstanding accomplishments being the design and construction of a 60 000 000-gal per day filter plant, the installation of 170 000 000-gal pumping equipment, construction of two 120-ton ice plants, with 30 000 tons of refrigerated storage, and rebuilding a gas plant.

Mr. Larmon spent the years from 1924 until his death in 1937 in water plant and sewage disposal work. He designed and constructed an 8 000 000 gal per day filter plant at Fort Pierce, Fla., which work also included the installation of a 1 150-hp Diesel engine with generator, and the revision of water rates. He undertook the valuation of the water plants at Wilkes-Barre, Pa., and Charleston, W. Va.; he investigated the design, construction, and operation of the principal water-works plants in Brazil, in South America; and for six years he was the Chief Engineer for the Midwestern Division of the Federal Water Service Company, including West Virginia, Ohio, and Illinois Water Service Companies.

Mr. Larmon was a born executive. He had a practical and scientific knowledge of engineering problems. Due to his many years of experience both in the United States and abroad, he was an authority on the design and operation of all types of water plants. He was modest about all his achievements. He was always the student—well informed, independent, and liberal in his views.

He had a charming personality and was courteous and gracious to all with whom he came in contact. He had a keen sense of humor which was always a source of pleasure to his friends. He was fond of sports, enjoyed hunting and fishing, and all kinds of outdoor life. His chief recreation was golf in which he was very proficient.

Mr. Larmon was a member of the American Water Works Association; Oriental Temple of the Mystic Shrine, at Troy, N. Y.; a Thirty-Second Degree Mason and a member of the Cambridge Valley Chapter, F. and A. M. He was also a member of the Presbyterian Church.

On June 28, 1904, he was married to Ruth May Beckerof, of Cambridge, N. Y., who, with two children, Alex Larmon, and Mary Larmon Short (Mrs. John Winchell), survives him, together with four grandchildren, Mary Lou and John Larmon Short, Charles and Peter Short; one brother, the Hon. Charles W. Larmon; and a niece, Frances Larmon.

Mr. Larmon was elected an Associate Member of the American Society of Civil Engineers on July 9, 1906, and a Member on June 24, 1916.

LASLEY LEE, M. Am. Soc. C. E.[1]

Died November 15, 1937

After an illness of only a few days duration, Lasley Lee died of pneumonia at his home in Columbus, Ohio. He was buried at Central College, Ohio, where his pioneer ancestors had settled shortly after the War of 1812.

Lasley Lee was born at Carbondale, Pa., on January 2, 1887, the son of the Rev. Charles and Myrtie Virginia (Lasley) Lee. He was educated in the schools of Carbondale and attended Lafayette College, at Easton, Pa. He was graduated from Massachusetts Institute of Technology, at Boston, Mass., with the degree of Bachelor of Science, in 1910.

In May, 1910, Mr. Lee accepted the position of Assistant Engineer in the City Engineer's Office, at Sioux City, Iowa, where he was employed on municipal work until August, 1911, when he resigned to accept the position of Junior Engineer in the Water Resources Branch of the United States Geological Survey, at San Francisco, Calif.

Mr. Lee was engaged in general stream-gaging work with the Geological Survey until May, 1914, after which he was connected with the investigation of the Hetch Hetchy Valley as a source of additional water supply for the

---

[1] Memoir prepared by a Committee of the Central Ohio Section consisting of C. Vernon Youngquist, Assoc. M. Am. Soc. C. E., *Chairman,* and F. H. Waring and J. R. Shank, Members, Am. Soc. C. E.

City and County of San Francisco until 1916. Following his California assignment, he was detailed to the Washington, D. C., Office, in July, 1916, where he served until January, 1917, when he was transferred to the Tacoma, Wash., Office of the Survey. After serving in the Tacoma Office for four years, his exceptional ability was recognized by his appointment in July, 1921, as District Engineer of the newly established Ohio District.

The State of Ohio at that time was sorely lacking in stream-flow data. Recognizing this lack and the great need in the State for this information, Mr. Lee spent the remainder of his life intensively carrying on this work with the result that Ohio became one of the foremost of the States in the quality of its gaging stations and stream-flow records.

Mr. Lee's remarkable industry is best indicated by the fact that when he came to Ohio only two gaging stations were being maintained in that State in co-operation with the U. S. Geological Survey; this number he gradually increased to more than one hundred. The result was that the ability to deal intelligently with water problems was greatly improved in Ohio.

In addition to carrying on this intensive program of establishing gaging stations and collecting and compiling stream-flow data, Mr. Lee was always interested in improving and developing instruments and structures used in stream-gaging work. These developments and improvements were described and detailed in many pamphlets, of which he was the author, under the general title of "Equipment for River Measurements." These pamphlets received widespread use and are recognized as authoritative sources of information.

Mr. Lee was endowed with a mechanical genius which resulted in his great interest in improving instruments and equipment used for river-measurement work. In collaboration with other members of the Geological Survey and the Department of Industrial Engineering at Ohio State University, he developed and improved river-sounding reels, wire-weight gages, electric contact tape gages, stream line sounding weights, and many other instruments and appurtenances used in river-measurement work. These instruments are now in general use all over the United States and have resulted in decided improvements in stream gaging.

Probably the most spectacular mechanical developments that Mr. Lee supervised were the power-driven rigs for obtaining discharge measurements of the Mississippi River, at Vicksburg, Miss., and Memphis, Tenn. This equipment made possible the accurate measurement of quantities of water with a degree of ease and facility which never before was deemed possible.

As a member of the Committee of the Geological Survey for Experimental Work at the National Hydraulic Laboratory, Mr. Lee was active in the arrangement and supervision of the various laboratory projects relating to measurements of river discharge which have been set up by the Survey for investigations at the Laboratory. These projects include "Studies of Artificial Controls"; "Investigations of Current-Meter Performance in Measurements of the Velocity of Water in Shallow Depths"; "Calibration of a Portable Parshall Flume"; "Study of Intakes for Gage Wells"; and "Measurements of Discharge near Bridge Piers."

He was co-author of about thirty *Water Supply Papers* containing records of stream flow in Ohio; also co-author of *Water Supply Paper 486,* "Water Powers of the Cascade Range," Part IV, Wenatchee and Entiat Basins; and *Water Supply Paper 492,* "Summary of Hydrometric Data in Washington, 1878–1919."

Mr. Lee was a member of the Delta Tau Delta (social) Fraternity, Sigma Xi (honorary) Fraternity, and Masonic fraternities among which were Scioto Consistory, Thirty-Second Degree Masons, and Aladdin Temple, Ancient Arabic Order of Nobles of the Mystic Shrine. He was a member of the American Geophysical Union, the Faculty Club of Ohio State University, President of the Columbus, Ohio, Massachusetts Institute of Technology Alumni Association, and Past-President of the Central Ohio Section of the Society.

He was married on July 11, 1921, to Mable V. Arthur, of Seattle, Wash., who, with a son, David, survives him.

Mr. Lee was a descendant of pioneer ancestors, his great-grandfather having settled a short distance from Columbus on land received for service in the War of 1812, a part of which he donated for the site of Central College. Lasley Lee displayed all the rugged virtues of his pioneer ancestry.

He was a hydraulic engineer pre-eminent in the highly specialized work of his profession. He was an untiring worker, devoted to engineering and scientific ideals. Personally, he was a staunch and loyal friend loved and admired by his associates. His death is a severe loss to his friends, to all who had the privilege of knowing him, and to the Engineering Profession. The memory of his kindly and courteous nature and genial disposition will always be cherished by his former associates.

Mr. Lee was elected an Associate Member of the American Society of Civil Engineers on March 11, 1919, and a Member on April 18, 1927.

ATTILIO FELIX LIPARI, M. Am. Soc. C. E.[1]

DIED FEBRUARY 13, 1938

Attilio Felix Lipari was born in Bompietro, Palermo Province, Italy, on February 12, 1890, the son of Joseph and Maria (Miserendino) Lipari. His mother was active in educational work in Italy. From his parents he inherited the studious and painstaking analytical qualities of mind which were so marked in his later life.

His father came to the United States in 1896 and established himself here. Five years later his family joined him in New York, N. Y., and it was in the public schools of this city that Attilio Lipari continued his education. He was graduated from Stuyvesant High School; and, in 1909, he entered Columbia University, to study Civil Engineering. He was graduated from Columbia in 1913 with the degree of Bachelor of Science in Civil Engineering.

---

[1] Memoir prepared by Rear-Admiral Frederic R. Harris, U. S. N. (*Retired*), M. Am. Soc. C. E.

Directly after his graduation, in July, Mr. Lipari was employed by the Standard Concrete Steel Company, Engineers and Contractors, as Assistant to the Chief Engineer—designing, estimating, and assisting in the field, on the erection of industrial buildings. He left this Company in January, 1917, to go with the New York Central Railroad Company in its New York City Office, on the design of structures and general drafting work, remaining there until April of the same year, when he became Assistant Engineer with the Octagonal Reinforced Floor Company on the design of reinforced concrete buildings.

Mr. Lipari was then employed by the Italian Commission which was in the United States, purchasing and inspecting war material, his work as an Assistant including the placing of orders, inspection, and shipment of ammunition and supplies. On September 10, 1917, he enlisted in the United States Army as a private, and was assigned by the War Department to duty with the Italian Purchasing Commission. On October 4, 1918, he was promoted to the rank of Second Lieutenant, from which he was honorably discharged on December 20, 1918. He was especially suited for this war work because of his thorough knowledge of the Italian language and his engineering training and experience.

After his discharge from the Army, Mr. Lipari immediately went with the J. G. White Engineering Corporation, of New York City, as Draftsman on the design of various industrial buildings, and continued with that firm until May, 1921. Two months later, he entered the employ of Mr. C. B. Comstock, as Structural Engineer on industrial plants and terminal work of various types, continuing in this position until May, 1925.

About that time Arthur L. Bobbs, Consulting Engineer of Chicago, Ill., became active in connection with a special type of design for hotel floors and similar building construction, and opened an office in New York City. Mr. Lipari went with him and was placed in charge of the structural design for the New York work. From January to May, 1927, he also did designing work with the General Engineering Management Corporation.

In May, 1927, Mr. Lipari was employed by the writer and Mr. Bobbs, who became associated as Consulting Engineers, the former having just been retired by the United States Navy Department. His work for Mr. Bobbs was in connection with the structural design of buildings and theaters, and as Assistant to the writer he received his first experience on water-front design work, principally graving and floating docks, so that in January, 1928, when Mr. Bobbs withdrew from the association, Mr. Lipari became the writer's Principal Assistant in charge of engineering design. His most important work in 1928 was the design of the graving dock for the Robins Dry Dock and Repair Company, in Erie Basin, Brooklyn, N. Y., the largest privately owned graving dock on the North Atlantic Coast. This work involved not only the design of the structure, but the planning of the actual methods and supervision of construction, as the owners had decided, after receiving bids, to undertake the work with their own force under the supervision and management of the Consulting Engineers.

This work was successfully completed in the latter part of 1929. During this same period Mr. Lipari was also in charge of the design work for the methods of construction of the W. G. Triest Contracting Company on two subways in the Borough of Queens, New York City, a notable piece of work being the special method of underpinning the Interborough Rapid Transit and Brooklyn Manhattan Transit Elevated Railroad structures, especially the approach to the Queensboro Bridge.

The engineering work of the writer was then taken over by Frederic R. Harris, Incorporated, Mr. Lipari becoming Vice-President in charge of design, and shortly thereafter Vice-President of Construction Management, Incorporated, a management of construction corporation. Among the important work handled by him was the investigation of the design of the foundations, pier, and bulkhead of the assembly plant for the Ford Motor Company, at Edgewater, N. J., of which Albert Kahn was the Architect; plant extension for the Todd Shipyards Corporation, in New York, Mobile, Ala., and New Orleans, La., including the design of a new ship repair plant for the same Company in Galveston, Tex.

He collaborated with the writer in connection with the preliminary investigations and reports on timber and steel floating dry docks for the Pacific Coast; on floating dry docks for various Gulf of Mexico locations, including one in Mexico; an investigation of the ship-building facilities of the United States for the Joint Conference of Ship Owners and Ship Repairers of the United States; an examination and report for the Port of Havana Docks Company, in Havana, Cuba; investigation of concrete foundation piles for the Department of Justice Building, Washington, D. C.; and various other activities.

In 1932, Mr. Lipari, as Vice-President of the Construction Management Corporation, designed the airplane plant of the Curtiss-Caproni Corporation, a subsidiary of the Curtiss-Wright Corporation, in Baltimore, Md., and also an airplane plant for the Curtiss-Wright Corporation, which, in modified form, was eventually constructed by that Corporation for the Chinese Government. He was also engaged on various water-front work and handling appliances, in connection with timber handling, including that of the J. C. Turner Lumber Company, at Irvington-on-Hudson, N. Y.

In 1936, Mr. Lipari went to Lima, Peru, and there, in conference with the Frederick Snare Corporation, Contractors for the new Port of Callao, investigated studies for a graving dock for the Republic, and prepared outline plans for such a dock, returning to New York in the fall of 1936, to take charge of the preparation of more detailed plans, and, eventually, under the writer, the supervision of the construction of this dock (Frederick Snare Corporation, Contractors), which at the time of his death was nearly completed.

During this same period, Mr. Lipari assisted and was active in the design of a new type of circular bottom floating dry dock, at Seattle, Wash., with a lifting capacity of 16 000 tons, which was successfully completed in 1937.

Shortly before his untimely death, Mr. Lipari had been engaged with the writer on special work for the United States Government in a review and examination of the plans for the new graving dock at Mare Island (California), working on the computations and design, and the method of construction involved; on a special type of graving-dock construction under consideration for use in the Hawaiian Islands; and on a general review of steel floating docks, with a view to recommending a type of construction for a structure of this kind of the largest capacity.

Since the end of the World War and with the Naval Disarmament Agreement, the United States Government had had no occasion to design or build additional graving docks or floating docks of the largest size, so that, consequently, on all these structures built or designed in the United States, Mr. Lipari had something to do with the design and was among the few experienced engineering experts on this type of work. Realizing his ability to serve his Government in case of an emergency requiring such assistance, all arrangements had been made for him to enter the Civil Engineer Corps of the United States Navy as a Lieutenant Commander in the Reserve. He modestly failed to take advantage of this opportunity, as, although not a pacifist, his retiring nature made him feel that even a reserve military title was something he did not want in time of peace, because, as he stated: "If I am here, and my adopted country needs me, I will then be available to them as a civilian or in any other capacity they want me."

Mr. Lipari was a devout Roman Catholic and a member of the congregation of St. Margaret's Church, in the Riverdale Section of The Bronx, New York; a member of the Holy Name Society; and unknown to many of his friends, was active in charitable work in The Bronx. He always believed in keeping his contributions and assistance to his fellow men a secret. He was modest and self-effacing, almost to the point of timidity. His circle of close friends was small, and he had few hobbies other than that of philately. On this subject he was an expert and one of the few authorities in the United States who knew the stamps and postal history of the Old Italian States.

He was highly interested in organizations and activities for the benefit of the Engineering Profession; was a registered Professional Engineer in New York; a member of the New York State Society of Professional Engineers; and, until shortly before his death, a member of the Society of American Military Engineers.

Mr. Lipari is survived by his father, Joseph (83 yr old); a brother, Dr. Angelo Lipari, head of the Italian Department of Yale University; and three sisters, Sarina, Angela, and Emma.

He was elected a Member of the American Society of Civil Engineers on March 10, 1930.

FRANK ALEXANDER McINNES, M. Am. Soc. C. E.[1]

DIED AUGUST 9, 1937

Frank Alexander McInnes, the son of John C. and Rachel J. (McBeath) McInnes, was born on November 27, 1856, in Fredericton, New Brunswick, Canada.

---

[1] Memoir prepared by Frank A. Barbour, M. Am. Soc. C. E.

He obtained his early education in the public schools of Fredericton, and in the High School of that city he came under the stimulating influence of its principal, George A. Parkin, who later became internationally known as the Executive Head of the Rhodes Scholarship Fund. In 1874, Mr. McInnes entered the University of New Brunswick, at Fredericton, from which he was graduated with the degree of Bachelor of Arts.

His first engineering experience was obtained in various preliminary and location surveys in New Brunswick and Maine. Later, he was Engineer in Charge of a preliminary survey for a so-called Air Line Railway between Boston, Mass., and New York, N. Y.

In 1888, Mr. McInnes found employment in the Engineering Department of the City of Boston and—except for an interval from 1915 to 1918—he continued to serve that city in various capacities until his retirement in 1924. From 1891 to 1895 he was an Assistant Engineer in the construction of improved sewerage; in 1895, he became Division Engineer of the Sewer and Water Division of the Public Works Department, which position he held until 1915. In 1918, after the separation of the Sewer and Water Divisions, he was made Division Engineer of the Water Division, and continued as such until 1924. From 1915 to 1918, he was employed as Engineer in charge of various improvements of the water system of St. John, N. B., Canada. Noteworthy in his service to the City of Boston was the installation of a high-pressure fire system.

Mr. McInnes was elected President of the New England Water Works Association in 1914 and was awarded Honorary Membership in 1929.

On his retirement, in 1924, from the service of the City of Boston, he became associated with William R. Conard, Assoc. M. Am. Soc. C. E., of Burlington, N. J., whom he represented in New England, in the testing of cast-iron pipe and other structural material and equipment. After 1924, Mr. McInnes also rendered consulting service in various water supply problems.

His most notable personal characteristic was rugged integrity and independence. Physically vigorous throughout his life, he continued to drive his car and visit his office until the day of his death at the age of eighty years. This physical capacity and his fearlessness were well shown in 1875 by his rescue from drowning, under most difficult conditions, of his boyhood friend, Sir Charles G. D. Roberts, the Canadian poet, who in various published articles has made grateful reference to the incident. For this exploit Mr. McInnes was given a watch by the citizens of Fredericton.

Generous in thought and deed, fortunate in a keen sense of humor, Frank Alexander McInnes had a great capacity for making and retaining friends, and for many years he was one of the most respected and best loved men in the water-works field.

He was married on October 16, 1893, to Laura E. Yerxa. His daughter, Dr. Frances McInnes, a member of the Medical Staff of Smith College, Northampton, Mass., survives him.

Mr. McInnes was elected a Member of the American Society of Civil Engineers on January 18, 1908.

LUDWIG THEODORE MAENNER, M. Am. Soc. C. E.[1]

DIED APRIL 6, 1937

Ludwig Theodore Maenner was born on October 1, 1863, at Neustadt, Bavaria, Germany, the son of Theodor and Josephine (Heigl) Maenner. He received his early education in the schools of Neustadt and was graduated from the Technical High School, at Straubing, Germany.

He came to the United States in 1883, and was employed by the Great Northern Railroad Company, at St. Paul, Minn., from July, 1890, until March, 1903, as Draftsman and Chief Draftsman in charge of map work, yard design, estimates for authorities for expenditures, and all other drawing-room work, under the jurisdiction of the Chief Engineer.

Mr. Maenner was employed from March, 1903, to June, 1906, by the Chicago, Rock Island, and Pacific Railroad Company, at Chicago, Ill., as Chief Draftsman in the Office of the Chief Engineer. In this position he had charge of the preparation of all plans and specifications of work assigned to the Chief Engineer; he also handled all the drafting-room work for the Real Estate and Tax Department and the Maintenance-of-Way Department, at Chicago.

In June, 1906, he accepted the position of Chief Draftsman with the Isthmian Canal Commission, with headquarters at Culebra, Canal Zone, Panama. He installed a system for filing maps and records, and prepared forms for cost-keeping and excavation statements. He also prepared statistical statements, in graphic form, of various expenditures, supervised the preparation of topographic maps of the Canal Zone, and land maps in connection with lawsuits, boundary disputes, etc. He completed his work with the Canal Commission in August, 1909.

Mr. Maenner's service with the Missouri Pacific Railroad Company began on September 1, 1909 when he was employed as Chief Draftsman in the Maintenance-of-Way Department, with general supervision of the Drafting-Room. When the Maintenance-of-Way and Construction Departments were consolidated in 1912, he was appointed Chief Draftsman in the Office of the Chief Engineer with direct supervision over all general drafting work, maintenance of records, etc. In 1917 Mr. Maenner was promoted to the position of Office Engineer, in which capacity he served faithfully and conscientiously until September 30, 1933, when at the age of 70 he was retired.

He was a man of strong character, ambitious, energetic, a good organizer, thorough in all his undertakings, loyal to his friends and employers, and was devoted to his family.

Mr. Maenner was a lover of chess and was President of the Western Chess Association from 1930 to 1933, inclusive, and a Director in 1934 and 1935. He organized the Missouri Pacific Chess Club in 1923, and was its President continuously until his death. He was a member of the Masonic Order.

---

[1] Memoir prepared by a Committee of the St. Louis Section, consisting of S. L. Wonson, M. Am. Soc. C. E., and William T. G. Topping, Esq., St. Louis, Mo.

He is survived by his widow, Mrs. Frieda Maenner, a son, Theodore H. Maenner, and two daughters, Mrs. Selma (Maenner) Huff and Mrs. Mabel (Maenner) Schwarz.

Mr. Maenner was elected a Member of the American Society of Civil Engineers on October 14, 1919.

FREDERIC MOLITOR, M. Am. Soc. C. E.[1]

DIED MARCH 12, 1938

Frederic Molitor was born in Detroit, Mich., on April 21, 1868, the son of Albert Molitor and Lucille I. (Goodell) Molitor.

Mr. Molitor was educated at Trinity Church School, New York, N. Y., and at Cornell University, in Ithaca, N. Y. On leaving Cornell he entered the service of the Central Railroad Company of New Jersey as Instrumentman and Draftsman. Later, he was employed by the Baltimore and Ohio Railroad Company advancing rapidly through the positions of Assistant Engineer, on the construction of the Kill van Kull Bridge; Principal Assistant Engineer, Kentucky Central Railroad Company, on the Huntington Bridge, at Cincinnati, Ohio; Engineer, Maintenance of Way, with the Chesapeake and Ohio Railway Company; and General Roadmaster, Louisville and Southern Railway Company. He constructed coal and freight piers for the Philadelphia and Reading Railway Company, and was in charge of construction of the Montauk Division, Long Island Railroad Company, in 1895, when he was appointed Chief Engineer of the Choctaw, Oklahoma and Gulf Railroad Company.

In the ensuing ten years Mr. Molitor built more than 1 000 miles of railroad in Askansas, Indian Territory, Kansas, and Texas, for the Choctaw and its Allied Companies (later incorporated in the Rock Island System), including many tunnels, heavy bridge work, and pneumatic foundations. As General Manager and Chief Engineer for the Midland Valley Railroad Company, he built and operated 350 miles of road in Arkansas, Oklahoma, and Kansas. A significant item in this work, showing Mr. Molitor's passion for direct thinking and accuracy in professional reporting, was the preparation of a Manual for Resident Engineers, which became a classic on Western railroads.

Mr. Molitor's broad experience and his ability as an Engineer and Administrator brought him to the attention of President Theodore Roosevelt, and, in 1905, he was appointed Supervising Railway Expert to the Philippine Government. He found the Islands with a railway system of 120 miles and left them, in 1907, with 550 miles.

In 1908, after a study of railroads and terminals in Europe, Mr. Molitor opened an office as Consulting Engineer in New York City, which he maintained until he retired from active practice in 1936. His services were sought by important financial houses for examinations of American railroads and South American development enterprises, and he was a trusted adviser of the United States Government. He was a member of the Special Panama Canal Committee and Chairman of the Committee of Valuation of Damages of the National Railways of Mexico.

---

[1] Memoir prepared by J. P. Hallihan and William J. Shea, Members, Am. Soc. C. E.

Mr. Molitor took an active interest in preparatory military training. Returning from an examination of the Brazilian Railways, he was commissioned, in January, 1917, as Major, Engineer Reserves, United States Army; and in July, 1917, he was assigned to duty with the Director General, Bureau of Military Railways, Office of the Chief of Engineers, U. S. Army. Major Molitor was promoted to the rank of Lieutenant Colonel in December, 1917, and assigned to duty with the 22d Engineers, U. S. Army, on June 1, 1918. On July 28, 1918, Lieutenant-Colonel Molitor was transferred to the staff of the Chief Engineer, American Expeditionary Forces (A. E. F.). On September 14, 1918, he was promoted to rank of Colonel; and on September 30, 1918, was appointed Officer in Charge, Engineer Supply Section, A. E. F.

Following the Armistice, Colonel Molitor directed a complete inventory of Engineer Supplies in France at all ports and depots, returned to the United States on March 6, 1919, and was honorably discharged from the Army on March 14, 1919. His interest in National Defense caused him to remain in the Corps of Engineers Reserve, until his transfer to the Auxiliary List, Reserve Corps, on March 18, 1931. In recognition of his war-time service Colonel Molitor was cited by General Pershing for " distinguished and meritorious service," and awarded the " Ordre de l'Etoile Noire," by the French Government.

An engineering service of far-reaching importance was undertaken by Colonel Molitor as Chairman of the Board of Economics and Engineering, created by the National Association of Owners of Railroad Securities in 1921, under the direction of the late S. Davies Warfield, President. Selecting as associates the late John Findlay Wallace, Past-President, Am. Soc. C. E., John F. Stevens, Past-President and Hon. M. Am. Soc. C. E., Walter W. Colpitts and W. L. Darling, Members, Am. Soc. C. E., and Professor Lewis B. Stillwell, with a staff of experts, Colonel Molitor made an exhaustive investigation of the operating and economic position of the railroad systems of the United States. Recommendations of the Board from the facts developed resulted in betterments of operating practice acceptable to the Interstate Commerce Commission and led to a better understanding of the economic and operating effects of proposed consolidations.

These few items selected from a crowded lifetime as an Engineer serve to indicate the high professional standing of Colonel Molitor. As a man he was imbued with a clear sense of justice and of civic and national duty. He enjoyed the high regard of his professional associates and of the contractors on the work he directed, as well as the respect and confidence of the financial leaders he served as Consultant. He was a leader in measures for professional advancement, and an active member of several technical societies, among them the American Institute of Consulting Engineers, the Institution of Civil Engineers of Great Britain, the American Railway Engineering Association, the Society of Engineers and Architects of Mexico, and the Society of American Military Engineers.

He was a member of the Century Club of New York, the Military Order of the Loyal Legion, and the Military Order of the World War.

He was married in 1896 to Katherine Jeffries, who survives him.

Colonel Molitor was elected a Member of the American Society of Civil Engineers on November 4, 1896.

DANIEL EDWARD MORAN, M. Am. Soc. C. E.[1]

Died July 3, 1937

Daniel Edward Moran passed quietly to rest at his home in Mendham, N. J., on July 3, 1937. For several years he had suffered a heart ailment and had been losing in physical strength, although his mental faculties remained vigorous to the end. He was buried in the family plot at Mendham.

Daniel Edward Moran was born on April 12, 1864, at Orange, N. J., the son of Daniel Edward and Annie Augusta (Blake) Moran. From 1866 to 1884, he lived in Brooklyn, N. Y., and attended the local schools, the last being Brooklyn Polytechnic Institute, from 1874 to 1880. He entered the School of Mines at Columbia University, in New York, N. Y., in the fall of 1880, taking the Civil Engineering Course, and was graduated in June, 1884, with the degree of Civil Engineer.

During his years at Columbia, Mr. Moran interested himself in various college activities, becoming a member of his class football team, School of Mines Editor of the *Columbia Spectator,* an Editor of the '84 School of Mines Yearbook, and a contributor to the *School of Mines Quarterly.* He was a member of the Delta Psi Fraternity.

After his graduation, in 1884, Mr. Moran designed and superintended the construction of a country residence for his mother. His personal notes state that in the spring of 1885, he entered the employ of the Delameter Iron Works, West 14th Street, New York City, "as apprentice at 50c per day, working 59 hours a week." He continued in this work until the spring of 1887 when he was employed as Instrumentman on a survey for the extension of the Nevada and California Railroad, north of Reno, Nev., owned by his uncle, Charles Moran. He quit this job in the fall of 1887 and returned to New York City *via* San Francisco, Calif., and Portland, Ore. Concerning this return trip, he writes that he went from San Francisco to Portland by "the new R. R. being built * * * there being a 20-mile gap which was covered by a 4-horse stage coach of the Wild West type. The Canadian Pacific Transcontinental line had been put through in 1886 but was still a rather 'sporty' trip."

---

[1] Memoir prepared by George L. Freeman, M. Am. Soc. C. E.

On his return, Mr. Moran had great difficulty in getting a position in New York City, but finally "found work at map making for Samuel McElroy for a few weeks in Brooklyn * * * and was fired because, as he said, I was getting more out of the maps than he was paid." For a short period, in 1887 and 1888, he was employed as Draftsman by the late William Barclay Parsons, Hon. M. Am. Soc. C. E., who then was "engaged in drawing plans for a proposed rapid-transit subway using the subgrade portions of private property, and only streets so far as necessary to cross from block to block."

Mr. Moran's long career as a Foundation Engineer began with his employment, early in 1889, by the late Charles Sooysmith, M. Am. Soc. C. E., a New York contractor who specialized in substructure work by the pneumatic, freezing, and other methods. Mr. Sooysmith first sent him to Iron Mountain, Mich., as Assistant Superintendent and Technical Observer on the construction of a mining shaft, for the Chapin Mining Company, to be constructed through a deep quicksand formation by the Poetsch-Sooysmith freezing method. A description of this work was afterward published by Mr. Moran.[2]

In the summer of 1889, the work at Iron Mountain completed, Mr. Moran was transferred to the position of Assistant Superintendent on the construction of the Deer Island Lighthouse at the entrance to the harbor at Boston, Mass. This structure was on an exposed reef extending south from the east end of Deer Island, its base being a circular shell of cast-iron plates founded on the reef, and backed up with concrete and brick masonry. Shortly after his arrival, he was placed in full charge of the work, which was completed before the end of the year despite bad weather conditions and the "dyspeptic army officer" in charge.

Late in 1889, Mr. Sooysmith had several pneumatic bridge foundation jobs in progress in the field, while designs for others were being developed in his office, and Mr. Moran was delegated to study designs and methods for this work, the study perhaps having been prompted by a serious accident which occurred about that time on a pneumatic job being constructed by Mr. Sooysmith at Needles, Calif. He visited a pneumatic job being constructed by Mr. Sooysmith at Wyoming, Pa., and interestingly records:

> "I found Christy (Supt.) laboriously breaking up rock, putting the pieces into sacks, hoisting the sacks two at a time into a common man lock, piling the lock as full as he could and operate, then locking out and rehandling the sacks to the dump. He used in hoisting the sacks a length of wire rope, which passed through a stuffing box in the head of the lock. I looked up all the data we had on the subject and started to design a safe and economical lock. Sooysmith told me not to waste time (his and mine) so I continued my studies out of office hours."

These studies led to the development of the first Moran air-lock, which Mr. Moran patented, and had constructed in 1892 by the Continental Iron Works, of Brooklyn, N. Y.

The late Alfred Pancoast Boller, M. Am. Soc. C. E., who was a specialist on drawbridges and a friend of Mr. Sooysmith, borrowed Mr. Moran in 1890 to design caissons for the McCombs Dam Bridge crossing the Harlem River at 155th Street, New York City. The main caisson was of steel construction, 19 ft wide by 100 ft long, and provided with two excavating shafts with locks located in the working chamber at the bottoms of the shafts, the soil to be removed through special buckets which formed a part of the lock arrangement. Later, Mr. Sooysmith was the successful bidder for the foundation work and, in 1892, placed Mr. Moran on the work as Night Superintendent. Both the lock buckets failed before the big caisson was sunk to its final depth, one becoming stuck at the bottom of the shaft, and the Moran lock, completed just in time, was secured to the top of the shaft and the bucket removed through it so that work could proceed.

---

[2] *Columbia School of Mines Quarterly*, No. 3, Vol. XI.

This was the first use of the Moran air-lock, and but one lock of this original design was built. It was of the top-and-bottom-door type, the top opening being fitted with two hinged doors meeting at the center, where the hoist rope passed through, with a stuffing-box to reduce air leakage. This lock marked a distinct advance in the speed and economy of pneumatic caisson work, as the arrangement of top and bottom doors made it possible to lower empty buckets through the lock and down the shaft directly to the floor of the working chambers, and to hoist the loaded buckets without rehandling or delay. Subsequent refinements made by Mr. Moran in the details of the air-lock, including the change to a single top door, resulted in the present widely used Moran lock.

Prior to the completion of the foundation for the McCombs Dam Bridge, late in 1892, Mr. Moran was sent to Sioux City, Iowa, where Mr. Sooysmith was to build the pneumatic piers for the foundations of the Pacific Short Line Bridge across the Missouri River. The engineer's plans had left the design of the caissons entirely to the contractor, the work was all ready to proceed and Mr. Moran's job was to design the caissons in the shortest time possible so that the work would not be delayed. He remained in Sioux City until the summer of 1893, when he was sent back to New York City by Mr. Sooysmith and put in charge of the foundation work for the American Surety Company Building, at the corner of Broadway and Pine Street. This was the second building in New York, or in the world, to be supported by pneumatic caissons.

Of this work, Mr. Moran writes that,

> "Many architects and some Engineers still questioned the reliability of Concrete, so the piers above the steel caissons (working chambers) were built of brick from Hudson River points. At first the bricklayers insisted on building level and plumb, not realizing that a caisson base is level only by accident. In sinking, the caisson might drop from 2 to 4 ft suddenly; then all the bricklayers would jump off the caisson."

The underpinning of buildings adjacent to caisson foundation jobs was then, as now, frequently necessary and, at that time, such underpinning was practically a monopoly in the hands of one New York contractor. Mr. Moran tried to convince Mr. Sooysmith that he should include underpinning with his other substructure work but the latter replied "these absurdly high buildings requiring caisson foundations are overdone. They are operated at financial loss to the owners and no more will ever be built." Mr. Moran thereupon decided that he would become familiar with underpinning work and prepare for the construction of future high buildings.

Continuing with Mr. Sooysmith until 1897, Mr. Moran then became Special Partner and Foundation Engineer with John Monks and Son, of New York City, remaining with that firm until about 1900. During this period, he designed and superintended the construction of pneumatic caissons for the water-works plant at Cincinnati, Ohio. In 1900 and 1901 he superintended the construction of a power canal and the foundations for a pulp mill and power-house at Great Bend, N. Y.

In 1901, with Franklin Remington and Edwin S. Jarrett, M. Am. Soc. C. E., Mr. Moran organized the Foundation Company, becoming its Chief Engineer and a Vice-President and Director. He continued with the Foundation Company until 1910, during which time it became the foremost builder of deep and difficult foundations in the United States and Canada. Mr. Moran was responsible for the engineering of many of its important foundation works.

From 1910 until his death, Mr. Moran was in private practice in New York City as a Consulting Engineer, under the name of Daniel E. Moran from 1910 to 1919; Moran, Maurice and Proctor from 1920 to 1928; Moran and Proctor from 1929 to 1935; and Moran, Proctor and Freeman from January, 1936, until his death.

His engineering works include the foundations for a great many buildings in New York City and elsewhere, such as the Woolworth and Municipal Buildings, Federal Reserve Bank, Equitable, Morgan, New York Stock Exchange, Barclay-Vesey Telephone, Bank of America, Chase National Bank, Bank of Manhattan, City Bank Farmer's Trust Company, Irving Trust Company, and many other buildings in New York City; the Federal Building, in Cincinnati, Ohio, Federal Building, in Pittsburgh, Pa., and Royal Bank of Canada, and Aldred Building, in Montreal, Que., Canada.

Mr. Moran was engaged on many important bridge projects among which were the Philadelphia-Camden, at Philadelphia, Pa., Mid-Hudson, at Poughkeepsie, N. Y., Ambassador, at Detroit, Mich., Huey P. Long, over the Mississippi River, at New Orleans, La., and the Suisan Bay, in California. He was for years Foundation Consultant to the Port of New York Authority, advising on foundations for the George Washington, Triborough, Bayonne Arch, and other bridges, and the Midtown-Hudson River Tunnel. Finally, came his greatest achievement, the foundations for the San Francisco-Oakland Bay Bridge, made feasible by the "domed" type of caisson which he devised and patented for use on this work.

He was a pioneer in the study of the properties of soils, his experiments on sands and clays, with home-made testing apparatus, pre-dating those of present-day soil technicians. He was among the first to understand the nature of volume change in clay and silt soils under loads and to apply this knowledge to actual foundation problems.

Although he was a leader in the development of pneumatic foundation methods, Mr. Moran, in his later years, because of their increasing cost, steadily oppposed their use in any work until he was convinced that no cheaper or more expeditious type of construction was possible. Here, again, we find him pioneering in the elimination of the very methods of construction he had spent so many years to develop. Outstanding examples of this advance in his practice were the deep foundations for the City Bank Farmer's Trust Company and The First National Bank Buildings, built by open methods in down-town New York, on sites where twenty years ago pneumatic caisson foundations would have been considered necessary.

Mr. Moran received the honorary degrees of Master of Science and Doctor of Science from Columbia University. In 1934, the Columbia Engineering Schools Alumni Association, calling him the "Dean of American Foundation Engineers" made him an Honorary Member. A year later, Dr. Nicholas Murray Butler, President of Columbia University, bestowed on him the Gold Medal of the Class of 1889 "for Eminent Achievement."

In December, 1896, Mr. Moran was married to Sarah V. Kelly, of Glasgow, Scotland. He is survived by his widow, his sons, Daniel E., Jr., Archibald A., and Hugh B., and by his daughters, Mrs. George Frazer and Mrs. Carl Bricken.

At the time of his death, he was a member of the American Institute of Consulting Engineers, The American Society of Mechanical Engineers, the Franklin Institute of Philadelphia, Pa., The Newcomen Society, of London, England; and the Engineers' Club, Downtown Association, University Club, Columbia University Club, and The New York Zoological Society, of New York City.

Mr. Moran was elected an Associate Member of the American Society of Civil Engineers on June 3, 1891, and a Member on January 1, 1896.

JOSEPH S. MORRISON, M. Am. Soc. C. E.[1]

DIED NOVEMBER 30, 1937

Joseph S. Morrison was born in Hedrick, Iowa, on January 8, 1874. His parents were John Morrison and Martha (Doolittle) Morrison. John Morrison was a Civil War Veteran, and was well known in Iowa because of his service in county office and the State Legislature. Joseph S. Morrison attended High School, at Hedrick, and was graduated from Iowa State College, at Ames, Iowa, in 1897, with the degree of Bachelor of Science in Civil Engineering. He received his Civil Engineering degree at Iowa State College in 1908. For a short time in 1895, he taught in a rural school near Guttenberg, Iowa.

The engineering career of Mr. Morrison began in 1898 as a Rodman on the Iowa Central Railway. He secured employment with the Chicago and

---

[1] Memoir prepared by W. J. Smith, Esq., Ottumwa, Iowa.

Northwestern Railway Company in 1899 as an Instrumentman, and during the next three years he was advanced to be Chief of Field Party on general surveys. He did instrument work for the Railway Company on the viaduct across the Des Moines River, west of Boone, Iowa, and made soundings and current observations for the double-track bridge over the Mississippi River, at Clinton, Iowa. He also worked a short time in the Bridge Designing Department of the Company, in Chicago, Ill. In 1903, he was engaged in construction for the Company in Nebraska and South Dakota. In 1904, he served as Assistant to the Division Engineer in Iowa and Minnesota, and was employed on maintenance and track work. In 1905, he served as Engineer in charge of revision work on yards and viaduct construction, at Long Pine, Nebr.

Mr. Morrison continued his service with the Chicago and Northwestern Railway Company as Assistant to the Division Engineer from 1906 to 1908, locating and constructing tracks in Michigan for the iron mines and logging camps. In 1909, he was in charge of a field party on the construction of the cut-off and viaduct at Valentine, Nebr. For the next three years, he had charge for the Company of the construction of 26 miles of track in Wisconsin and during this time, also supervised the construction of bridges across the Wisconsin and Yellow Rivers, and the building of terminal yards at Wyeville, Wis. In 1912, he had charge of the construction of 10 miles of track in Illinois. From February, 1913, to May, 1914, he was engaged on Federal valuation on the St. Louis, Peoria and Northwestern Railway.

Mr. Morrison did his last railway engineering work in 1914, and then entered the service of the Iowa Highway Commission. It was his good fortune to enter highway work at the time the extensive use of automobiles and trucks made necessary the building of a system of surfaced highways. He was appointed District Highway Engineer of the 5th District, with headquarters at Ottumwa, Iowa. In 1914, there were no surfaced highways in Southeastern Iowa outside the cities and towns. The present system of surfaced roads in the 5th District was built under his supervision. From 1914 to 1919, his duties, in general, were to advise the County Boards of Supervisors relative to the standards required by the State Highway Commission.

The construction of Federal Aid Highways began in 1919 and, at that time, Mr. Morrison began directing a force of assistants on construction work. He had an active part in locating lines, making surveys and plans, and supervising construction. At present (1938) there are 1 379 miles of primary roads in the District, and he was familiar with every structure. A few of the larger bridges built in the southeastern part of Iowa, during Mr. Morrison's service as District Engineer, are those over the Des Moines River, at Keokuk, Ottumwa, and Belle Fountain, Iowa, and two bridges over the Iowa River, at Columbus Junction, Iowa. In 1925, the State Highway Commission became responsible for the maintenance of primary roads. As District Engineer, Mr. Morrison had charge of this work in the 5th District. In 1925, the primary roads in the District were constructed of earth and gravel, and maintenance work consisted of smoothing the surface following rains. In the next few years, the requirements of road maintenance increased, and permanent garage buildings were erected by the State in each county, much equipment was purchased, and a force of 200 men was employed to keep the roads in good condition during all seasons.

On September 5, 1905, Mr. Morrison was married to Sophia Schott. During the time he was engaged in railway work they made their home in the localities near his work. Since 1914, however, they had lived in Ottumwa. He is survived by his widow and four children, John, George, and Alice, and Mrs. George Welz.

Mr. Morrison and his family have had a wide acquaintance with students and graduates of Iowa State College, and it is rather unusual to find a family in which so many members have had an interest in the same school. He had four sisters and one brother who attended Iowa State. He and Mrs. Morrison and three of their children are graduates, and their youngest son is a student at Iowa State College. His father was a Trustee of the college in the early Nineties.

His chief interests in life were his work and his family, and he devoted practically all his time to them. Most of his friendships were made with those who had contacts with him through his work. He enjoyed a good story to the extent of appreciating those told on himself. He was able to delegate authority to his subordinates and judge them on the results obtained. When he assigned a task he expected good work, but he did not insist on his own methods, or try to force his opinions on others. He encouraged young men to accept responsibilities and when mistakes were made he was willing to accept his just share of the fault. When it was necessary to criticize an employee he could do it thoroughly without offending. His employees liked to work under his supervision and were loyal to him.

Mr. Morrison was elected a Member of the American Society of Civil Engineers on August 31, 1915.

JAY JOHNSON MORROW, M. Am. Soc. C. E.[1]

DIED APRIL 16, 1937

Jay Johnson Morrow was born at Fairview, W. Va., on February 20, 1870. He was the son of James Elmore Morrow and Clara (Johnson) Morrow. His father was a graduate of Jefferson College, at Canonsburg, Pa. (later Washington and Jefferson College, Washington, Pa.), and a teacher and professor in a number of schools in West Virginia and Western Pennsylvania. James E. Morrow entered the Union Army during the Civil War and rose to the rank of Captain. In 1871, he became President of Marshall

---

[1] Memoir prepared by Brig. Gen. Herbert Deakyne, U. S. Army (*Retired*), M. Am. Soc. C. E.

College at Huntington, W. Va., and, later, was a Teacher of Mathematics and Principal of Schools in Pittsburgh, Pa., and vicinity. He was a man of culture, fond of learning, a scholar in Latin and Mathematics, and had a great talent for teaching.

On the maternal side of the family, Clara (Johnson) Morrow was the daughter of John Jay Johnson, and possessed an acute and active mind combined with strong practical sense.

Jay Johnson Morrow was the second of eight children in this family. With this background, he grew up in an atmosphere that fostered his mental development. The family lived on the limited income of the father, but the home surroundings stimulated an interest in books and study, and a desire to excel in the tasks of the hour. Jay was graduated from the High School in Allegheny, Pa., at the age of 14, and then went to work as a Clerk and Bookkeeper at a modest salary. At 17 he secured an appointment to the United States Military Academy, at West Point, N. Y. He entered the Academy on June 16, 1887, and was graduated on June 12, 1891, standing No. 5 in a class of 65 members. He was assigned to the Corps of Engineers, United States Army, and served as a member of it until his retirement at his own request on August 5, 1922.

His first service after graduation from the Military Academy was at the Engineer School of Application at Willets Point, Long Island, N. Y., later, Fort Totten. Lieutenant Morrow completed the course at the Engineer School in 1894. In 1895 he returned to West Point as an Instructor in Practical Military Engineering, remaining on that duty until September, 1896. In addition to his duties as an Instructor, he was engaged in the construction of a new water-supply system for the Post of West Point. From September, 1896, to August 1898, he was on duty in the Washington, D. C., Engineer District and was in responsible charge of the construction of fortification works and submarine mining casemates at Fort Washington, Maryland.

Lieutenant Morrow was at the Military Academy again from August, 1898, to February, 1899, as Instructor in Civil and Military Engineering. He was then detailed on fortification construction in New York Harbor and was in charge of fortification work at Fort Wadsworth and Fort Hamilton. In August, 1899, he returned to West Point and from that time until March, 1901, was Instructor and Assistant Professor of Civil and Military Engineering. During this time, he made two surveys of the Post of West Point.

He was promoted to the rank of Captain in February, 1901, and from that time until June of the same year, was at Fort Totten, in command of a Company of Engineer Troops which he then took to the Philippine Islands. He remained in the Philippines until November, 1903, during which time he had charge of road construction and improvement, and of the design and construction of pile and masonry wharves at various points in the Islands.

Returning to the United States Captain Morrow was detailed as Assistant to the Engineer Commissioner of the District of Columbia. As such he had charge of the Surface Division, which included street, sidewalk, and alley pavements, highway construction and extension, surveys, street parking, and inspection of asphalt and cement. In May, 1907, he became the Engineer Commissioner of the District, and held this position until December, 1908, having been promoted to the grade of Major in January, 1908.

Major Morrow's next duty was in charge of the Washington, D. C., Engineer District and of the water supply of the City of Washington. This tour continued until March, 1910, when he was transferred to Portland, Ore., in charge of river and harbor work. He remained in charge of this important District until June, 1915, with a temporary interruption of three months—from December, 1912, to March, 1913—during which time he was Chairman of the Alaska Railroad Commission.

He was promoted to the rank of Lieutenant Colonel in March, 1915, and in June of that year he began his connection with the Panama Canal, first as Assistant to the Engineer of Maintenance and, later, as Engineer of Maintenance. This duty was interrupted by the entry of the United States into the World War. Colonel Morrow's first war duty was the command of the Fourth Engineers at Vancouver Barracks, Washington, and at Camp Greene, North Carolina. He had been promoted to the temporary rank of Colonel in August, 1917. In May, 1918, he took his regiment to France.

Shortly after reaching France, he was promoted to the rank of Brigadier General, and when the First American Army was organized there, he was detailed as its Chief Engineer. He proceeded to organize this important command to cover the many and varied services required to carry on the engineer work of an army in the field. He was Chief Engineer of the First Army during the engagements of Chateau Thierry, Vesle River, St. Mihiel, and Verdun-Argonne. General Morrow had a short period of duty as Chief Engineer of the Third Army, and was then made Deputy Chief Engineer of the American Expeditionary Forces in France. For his service during the war he received the French decoration of the Legion of Honor.

After the Armistice he returned to the United States and reverted to his regular rank of Lieutenant Colonel. He was in command of the Post and the Engineer School at Camp Humphreys (later, Fort Belvoir), Virginia, from January to May, 1919. Colonel Morrow then resumed the duty he had at the beginning of the war, that of Engineer of Maintenance of the Panama Canal. He continued in this position until March, 1921, when he was advanced to the responsible duty of Governor of the Panama Canal. In the meantime, he had been promoted in April, 1920, to the regular rank of Colonel. In August, 1922, at his own request, he was placed on the retired list of the U. S. Army with the rank of Colonel, after more than thirty-five years' service. This did not terminate his duty as Governor, which continued until October, 1924.

After his Panama Canal service he held another responsible position from March, 1925, to June, 1929, as the United States Member and Chairman of the Special Commission on Boundaries, Tacna-Arica Arbitration.

On June 21, 1930, in accordance with the Act of Congress of that date, he was advanced on the retired list to the grade of Brigadier General, because he had held that rank during the World War.

General Morrow was married on October 15, 1895, to Harriet M. Butler, the daughter of Brigadier General John G. Butler, U. S. Army. She died on April 24, 1935. They had no children.

Any account of the life of General Morrow would be incomplete without reference to his brother, the late Dwight W. Morrow. The latter was born January 11, 1873, and was thus about three years younger than General Morrow. He was anxious to obtain an education and hoped to succeed his brother as the Cadet at West Point from the Congressional District in which they lived. With this in view Dwight entered a competitive examination for the appointment and came out first, but was denied the appointment because his brother had already represented the District.

Dwight Morrow despaired for a time of obtaining an education, but after his brother's graduation from West Point in June, 1891, it was arranged that he should go to Amherst College, at Amherst, Mass. Out of his pay as a Second Lieutenant, Jay Morrow was able to save enough to lend his brother the funds that enabled him to go through college. His subsequent career as a member of an important law firm in New York City, as a partner in the banking house of J. P. Morgan and Company, Ambassador to Mexico, and United States Senator, justified the effort it required to finance his college course. Harold Nicolson, in his book on the life of Dwight Morrow, quotes General Morrow as saying of the money he advanced for Dwight's education: "But there is no one who can say that these were not the best investments that I ever made."

There was a strong bond of affection between General Morrow and Dwight's daughter, Anne Morrow. This dated from her infancy when she exhibited a decided liking for her uncle. Her marriage to Charles A. Lindbergh made her a public character of first importance. The tragedy of the kidnaping and death of her infant son was a source of great sorrow to General Morrow. One of the last things he did was to cross the Atlantic to pay a visit to her and Colonel Lindbergh, and he had just returned from this trip when he died.

During his later years General Morrow lived in Englewood, N. J., where his brother, Dwight, made his home. He took a great interest in West Point and in the reunions of his Class. He contributed much to the success of the Fortieth Reunion in 1931, and the Forty-Fifth Reunion in 1936 by arranging for the wives of his classmates to be guests during the reunion periods at the country estate of his nephew near West Point. He provided transportation so that they could attend the ceremonies at West Point in comfort.

General Morrow was a lover of the opera and is said to have attended 600 performances over a period of 40 years. The newspapers reported that he commuted from Panama and Chile to New York to attend the opera. This exaggeration of statement merely serves to emphasize his devotion to the art.

General Morrow was not only a capable engineer and an efficient administrator, but he was also fond of athletic sports. In his younger days he was a good tennis player and he also played football and baseball. He was well-rounded both mentally and physically. His mental grasp was broad and comprehensive. This was particularly noticeable in France during the

World War. Detailed as Chief Engineer of the First American Army created in France, he had to organize that service with its great variety of functions to be performed. Roads, railroads, water supply, electrical and mechanical work, camouflage, shelters, obstacles, demolitions, mining —these were some of the things to be looked after, with special troops for many of them. To organize such a service, to secure the Officer Personnel to administer it, and to handle the troops to do the work, made a task of the first magnitude.

The Governorship of the Panama Canal is also a position calling for high ability. It involves not only the engineering work of keeping the Canal in operation, but also many other tasks, such as relations with the Republic of Panama, with the military forces on the Isthmus, with the ships of all nations using the Canal, with labor, with the civilian population on the Isthmus, and with the dignitaries, American and foreign, continually moving through as passengers.

To handle successfully such duties as these requires alertness, breadth of view, and a well-balanced mind.

General Morrow was elected an Associate Member of the American Society of Civil Engineers on June 5, 1901, and a Member on March 1, 1904.

THOMAS SARSFIELD O'CONNELL, M. Am. Soc. C. E.[1]

DIED NOVEMBER 3, 1937

Thomas Sarsfield O'Connell was born in San Francisco, Calif., on July 14, 1888, the son of Thomas Sarsfield O'Connell and Gussie (Lovell) O'Connell. He was a lineal descendant of the same family as William, Cardinal O'Connell, and was a direct descendant of Patrick Sarsfield, famed Irish patriot, for whom he was christened. As a youth, he went to Arizona, where he attended preparatory school. His technical education was received at the University of Arizona, at Tucson, Ariz., and the United States Military Academy, at West Point, N. Y., where he was a member of the Class of 1911.

Mr. O'Connell's first practical experience in his profession was with the Sud Pacifico de Mexico. His career in the Arizona State Highway Department began in 1913 and was unbroken, except during the World War. In May, 1917, he was commissioned as First Lieutenant in the Army and served overseas with the 362d Infantry, 91st Division. After leaving the Army in May, 1919, he again entered the service of the Arizona State Highway Department as Locating and Construction Engineer, being promoted to District Engineer in 1924, which position he held until his appointment as State Engineer, on April 1, 1931.

As State Highway Engineer of Arizona, Mr. O'Connell made an enviable record as a progressive road builder. He was recognized by engineers throughout the nation as an authority on design, construction, and the financing of highways. He was a strong advocate of Federal aid for Western highways, and was instrumental in placing the problems of the Western States before Congress. His untiring efforts in obtaining a more equitable Federal aid for the Western States was a large factor in the development of the splendid highway system of the West. He was progressive—always ready to adopt new ideas that he considered sound.

---

[1] Memoir prepared by a Committee of the Arizona Section, consisting of J. R. Van Horn, E. V. Miller, and Jane H. Rider, Assoc. Members, Am. Soc. C. E.

Mr. O'Connell helped to pioneer the modern low-cost highway surfaces, utilizing light asphaltic oils. Without this type of surface, the fine dustless roads which Arizona now has, would not have been economically possible. He did much to further the modern trend of highway design, such as roadside improvement, soil stabilization studies, prevention of soil erosion, divided highways, etc.

He took an active part in the affairs of his profession, being a Past-President of the Western Association of State Highway Officials, member of the Executive Committee of the American Association of State Highway Officials, as well as Chairman of the Committee on International Highway Relations of that organization. He was a member of the Board of Directors of the American Road Builders' Association.

Mr. O'Connell was considered by all who knew him as a man of great courage, force, and ability, combined with a courteous personality and an unswerving loyalty to his employees. The greatest compliment that can be paid him is exemplified in the love and respect borne him by the members of his profession.

He was married in March, 1930, to Inez Elmer, who survives him.

Mr. O'Connell was elected an Associate Member of the American Society of Civil Engineers on July 11, 1927, and a Member on October 14, 1930.

ROBERT VANCE ORBISON, M. Am. Soc. C. E.[1]

DIED OCTOBER 6, 1937

Robert Vance Orbison was born in Sidney, Ohio, on February 20, 1882, the son of David Rush and Emma Jane (Ewing) Orbison. The family traced its ancestry to good old Irish stock which, no doubt, accounts for the good nature and tireless energy which "Bob" Orbison evidenced throughout his life.

As a boy, he attended the public schools in his native town, and was graduated from the Sidney High School in 1900. He then attended the Utah State Agricultural College, at Logan, Utah, and took up the study of Civil Engineering.

Upon leaving college, Mr. Orbison entered the service of the Utah Sugar Company, at Garland, Utah. The Company, at that time, was engaged in reclaiming and developing a large area in Northern Utah. During the 3½ yr that Mr. Orbison remained with the Company, he advanced from Chainman to Field Engineer, and had an important part in locating and constructing an irrigation system, dams, and dividing the Company's holding into farms and town sites.

---

[1] Memoir prepared by Morris S. Jones, M. Am. Soc. C. E.

Leaving Utah in 1905, Mr. Orbison entered the employ of the Yosemite Valley Short Line Railroad Company, which line was then being built through the precipitous gorge of the Merced River into the Yosemite Valley. This railroad was the first means of easy travel into this beautiful valley.

In 1907 he became associated with the Stone and Webster Company as a Traveling Civil Engineer, and for three years was engaged in the construction of electric street railways in various cities, in Texas.

This work being practically completed in 1910, Mr. Orbison moved to Los Angeles, Calif., where he secured a position with the Janss Investment Company, a large realty company then engaged in subdividing and marketing large tracts of land in and around Los Angeles. In addition to sub-division work and the installation of street improvements, Mr. Orbison had charge of the installation of several moderately large water distribution systems, including the design of the pumping plants and reservoir.

In May, 1912, he became associated with the City Engineer's Office of the City of Pasadena, Calif., becoming Chief Deputy a year later. In December, 1914, he was appointed City Engineer in charge of the office. At that time, the most important problem before the City was to find an adequate means of sewage disposal. The disposal works then in use were very much overloaded, and created such a nuisance that the City was in constant danger of facing damage suits.

In 1915, the activated sludge process for sewage disposal was in its infancy. Experimental plants had been established in a few places in the United States, most notably in Milwaukee, Wis., but the superiority of this method had not then been established. After a visit to the Milwaukee Plant, Mr. Orbison built an experimental plant and laboratory and conducted tests which led to his recommendation for the construction of an activated sludge plant. The Pasadena Sewage Disposal Plant, built as a joint project by the Cities of Pasadena, South Pasadena, Calif., and Alhambra, Calif., in accordance with Mr. Orbison's design, has been in continuous operation since 1924, with most satisfactory results.

In March, 1920, after an enviable record as City Engineer of Pasadena, Mr. Orbison was called to be the first City Manager of the neighboring community of South Pasadena. While in the service of South Pasadena, he acted in the dual capacity of City Manager and City Engineer. During the period he was in charge there, the largest program of municipal improvements in the history of the city was completed. The Municipal Water Department of South Pasadena was organized by Mr. Orbison to take over the privately owned water systems then supplying the major part of the city. He was also instrumental in securing a new source of water supply for the city.

In August, 1925, after having been in charge of the affairs of the City of South Pasadena for 5½ yr, he was called back to Pasadena, this time as City

Manager. At that time Pasadena was entering into a period of most rapid growth and development. Under his régime, the $4 000 000 Civic Center Project, which consisted of a new City Hall, Library, and Municipal Auditorium, was completed. Nearly $5 000 000 worth of street improvement work was done under his supervision, and $10 000 000 in bonds were voted for the construction of the San Gabriel Water Project which was to bring into Pasadena a supply of water from the San Gabriel River.

In 1931, Mr. Orbison tendered his resignation to the City Board of Directors. For a time after leaving the service of Pasadena, he entered the consulting field in sanitary engineering. With the passing of the Federal Housing Act in 1933, he went to Washington, D. C., in the capacity of Federal Housing Engineer. Two years later he returned from the nation's Capital to accept a position with the California State Government in the Veterans' Bureau, appraising and investigating loans to World War Veterans, which position he held at the time of his death.

Mr. Orbison passed away on October 6, 1937, at his home in South Pasadena, his death being due to a sudden heart attack. Although he had not been in the best of health for some years, his death was most unexpected and a great shock to his many friends in Southern California.

"Bob" Orbison was a kindly man, witty, and always good company. He was absolutely fair and had the respect and loyalty of all those who worked with him. He was a hard worker himself, an excellent executive, and could direct others easily and efficiently. His greatest interest was in sanitary engineering, on which subject he contributed many articles to technical publications.

He was married to Evelyn Alice Kanouse, in El Paso, Tex., on November 23, 1909. He is survived by his widow, a daughter, Phyllis Orbison, his mother, Mrs. Emma J. Orbison, and two brothers, Harold E. Orbison and James E. Orbison.

He was a Thirty-second Degree Mason and a Shriner. He was exceedingly active in the affairs of the Los Angeles Section of the Society. He served as Vice-President of the Section in 1927, and was elected President in 1928.

Mr. Orbison was elected a Member of the American Society of Civil Engineers, on August 28, 1922.

FRED BAILEY OREN, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 29, 1936

Fred Bailey Oren was born in Watseka, Ill., on September 16, 1880, the son of Asa Oren and Mary (Frazier) Oren. His father came of a Quaker family whose home was in a village near Wilmington, Ohio. His mother was a Watseka girl. The removal of the family to Englewood came when his father purchased a drug store in Chicago, Ill. The boy's Grammar School education was obtained at Watseka, but his High School work was taken at Englewood High School, in Chicago, from which he was graduated in 1897, at the age of seventeen years.

---

[1] Memoir prepared by Winfred Dean Gerber, M. Am. Soc. C. E., as a Committee of the Central Illinois Section.

Mr. Oren entered upon his engineering career shortly after his graduation from High School, when he entered the employ of the Engineering Department of the Illinois Central Railroad Company as Rodman.

About 1902 he was made Resident Engineer on the construction of the Illinois Central Bridge over the Little Wabash River, near Watson, Ill., with headquarters at Effingham, Ill. In 1903, he was made Division Engineer, with headquarters at Water Valley, Miss., and, later, became Roadmaster with headquarters at Champaign, Ill.

While Roadmaster at Champaign, Mr. Oren decided to go into the contracting business and, in 1919, undertook the execution of his first contract, an 8-mile section of highway paving on Old Route No. 11 of the Illinois Highway System, near St. Elmo, Ill. The contracting firm then was known as Mautz and Oren.

Out of the partnership of Mautz and Oren, there was formed in 1923 a corporation, the officers of which were A. H. Mautz, President; W. P. Mautz, Vice-President; with Mr. Oren as Secretary-Treasurer. This firm continued in the contracting business so well started, specializing in all fields of highway construction for both the Illinois State Highway Department and for various County Highway Departments.

As a business man, Mr. Oren had the respect and admiration of all who knew him; and his firm ranked high with the State Highway Department.

On June 21, 1903, he was married to Aldora Forrest Jaycox, of Watson, Ill. After severing his connection with the Illinois Central Railroad Company, he established his residence in Effingham, Ill.

He was a great fisherman and thoroughly enjoyed his vacations at his winter home in Biloxi, Miss. It is said that he knew the fishing grounds of the Gulf and its tributaries as few other men did, and could always be counted upon to bring in a good catch.

Mr. Oren was elected a Member of the American Society of Civil Engineers on April 14, 1919.

RAYMOND STANTON PATTON, M. Am. Soc. C. E.[1]

Died November 25, 1937

Raymond Stanton Patton was born in Degraff, Ohio, on December 29, 1882, the son of Oliver and Ida M. (Cloninger) Patton. His early education was obtained in the public schools at Sidney, Ohio. He received his technical training at Adelbert College of Western Reserve University, at Cleveland, Ohio, from which he was graduated in June, 1904, with the degree of Bachelor of Philosophy.

---

[1] Memoir prepared by J. H. Hawley, M. Am. Soc. C. E.

Within a month after his graduation Mr. Patton was appointed an officer in the Field Corps of the United States Coast and Geodetic Survey. He rose to the position of Director of the Survey in 1929, in which position he served until his death.

Mr. Patton's first field work began in August, 1904, on the Atlantic Coast where he served as a Junior Officer on the Coast and Geodetic Survey ship *Hydrographer,* engaged in Coast Pilot revision, and with a shore party carrying on topographic surveys in Virginia. This was followed in 1906 by assignment to duty on the Survey ship *Gedney,* operating in Southeastern Alaska.

In the spring of 1907, he began a 3-yr tour of duty in the Philippine Islands where, as a Junior Officer on the Survey ships *Romblon* and *Research,* he took part in surveys of various localities including Tanon Straits, the north coast of Negros Island, and the southeast coast of Luzon. For a part of this time he was also a member of several shore parties engaged in surveys of Mindanao, Bohol, and the Camiguin Islands.

During this period, conditions in the Philippine Islands were far different from those at present. The Insurrection was not far in the past and the Filipinos, especially in areas away from centers of population, were in a state of unrest, and in many cases were resentful toward Americans. Living conditions, affecting health, recreation, and even the ordinary comforts, were far from satisfactory. In this, as well as in his other early assignments, Mr. Patton's cheerfulness in enduring hardships and his zeal in the performance of his duties indicated the pioneering spirit and devotion to the interests of the Service which characterized his entire career.

Upon his return to the United States in 1910, he was engaged on various projects along the Atlantic Coast, including triangulation in Massachusetts and resurveys of Delaware Bay and Albemarle Sound until the summer of 1911 when, after a brief assignment as Executive Officer of the Survey ship *Bache,* on the Gulf Coast, he again went to Alaska as Executive Officer of the Survey ship *Patterson.* Later, in the same year, this ship operated on the Pacific Coast of the United States and in the western approaches to the Panama Canal. In 1912, Mr. Patton was given command of the Survey ship *Explorer,* and for the following three years was in charge of the work of that ship in Alaska, of which a survey of the approaches to the Kuskokwim River was especially important.

Returning to Washington in 1915, Captain Patton was placed in charge of the compilation of the volumes of the *Coast Pilot* published by the Coast and Geodetic Survey to provide mariners with information required for coastal navigation in addition to that shown on the nautical charts. In this capacity he had charge of the field and office work required for the periodic revision of the *Coast Pilot* and was the author of two volumes, the 1916 edition of the Alaska *Coast Pilot* for the region from Yakutat Bay to the Arctic Ocean, and the 1917 edition of the *Coast Pilot* for the Pacific Coast of the United States.

With the entry of the United States into the World War, Captain Patton was anxious to join the armed forces, and in September, 1917, together with a number of other officers of the Coast and Geodetic Survey, he was transferred by Executive Order to the Navy Department and served as a Lieutenant and, later, as a Lieutenant Commander in the Naval Reserve Force for the duration of the war.

After the conclusion of this service he returned to the Coast and Geodetic Survey and, in 1919, was appointed Chief of the Chart Division. It was during his tenure in this office that his ability as an organizer and executive began to have considerable effect on the progress of the Survey's work. For some time prior to his appointment to this position, it had been realized that the Bureau's service to maritime interests was impaired by the rather lengthy period required for the compilation of nautical charts following the completion of field surveys. This condition, however, had been regarded as inevitable on account of the careful and painstaking work which is always required when extreme accuracy is essential and the arduous nature of many of the processes involved.

Recognizing the need for improvement in this respect, Captain Patton immediately applied himself to the problem and met with marked success. Through a complete re-organization of the Division, the adoption of a comprehensive production schedule, and his constant encouragement of those under him in the development of more efficient methods and equipment, the period necessary for chart compilation was gradually reduced to about one-third of the time formerly required, with no impairment in quality.

In connection with his work in the Chart Division he became interested in beach erosion and devoted extensive study and research to this subject. In 1921, the New Jersey Board of Commerce and Navigation asked Secretary of Commerce Hoover to designate a representative of his Department to serve on an engineering advisory board created to study erosion problems in that State, for the purpose of devising better means of protecting the highly improved and valuable sections of the coast. Captain Patton was named by Secretary Hoover for that duty, and co-operated actively in the execution of the project. The studies made were embodied in part in two reports, one published in 1922 and one in 1924. These reports form the basis for an active participation by the State of New Jersey in the problem of shore protection.

In 1925, he was appointed a member of the Committee of the National Research Council on Shoreline Investigations and in the following year was named its Chairman. Knowledge of the importance to New Jersey of coast protection suggested to the Committee that a similar situation might exist in other States to such an extent as to constitute a national problem in which the Council would be justified in becoming interested. Inquiry along the Atlantic and Gulf Coasts revealed that almost every State was struggling with conditions similar to those in New Jersey, each State or community groping its way toward solutions independently of the others.

Since the National Research Council had neither the funds nor the personnel for a direct attack upon the problem, the obvious method was to link together all these isolated efforts into a united one. This was accomplished through the creation of the American Shore and Beach Preservation Association organized in December, 1926, through joint action by the Committee on Shoreline Investigations and the Governors of the Atlantic and Gulf Coast States. Captain Patton took a major part in its formation, was its Secretary-Treasurer until June, 1929, and a Director until his death. On account of his extensive knowledge of this subject and of the activities and records of the U. S. Coast and Geodetic Survey he was frequently called upon to serve as an expert witness in litigation concerning riparian property boundaries.

He continued as Chief of the Chart Division until April 29, 1929, when he was commissioned by President Hoover as Director of the Coast and Geodetic Survey, succeeding E. Lester Jones, M. Am. Soc. C. E., who died on April 9, 1929. At that time, he held the relative rank of Captain in the Navy. In March, 1936, Captain Patton was promoted to the rank of Rear Admiral.

Under the leadership of Admiral Patton the modernization of survey methods and equipment, which had been initiated by Colonel Jones, was continued and accelerated. Through his own progressiveness and the encouragement he constantly gave to his colleagues, great advances were made in the efficiency of all branches of the Survey's work. Many of the improvements effected were at the start highly experimental and their final success was due in no small measure to his vision of their possibilities and his unfailing assistance in their development.

An outstanding achievement of this period was the expansion of the operations of the Coast and Geodetic Survey during the depression years from 1933 to 1935. From the beginning of the depression Admiral Patton realized that there was a vast amount of work of this character which could be carried on to advantage throughout the country and that it was well adapted to the relief of unemployment, especially in the case of men with engineering training. With the effective co-operation of the officers of the Society and others vitally interested in the conditions confronting the Engineering Profession at that time, he was able to secure substantial allotments of emergency funds which were utilized to provide employment for a large number of engineers and, at the same time, to accomplish an extensive amount of worth-while work much of which had been urgently needed for some time.

He derived great pleasure from the success of this undertaking and often expressed his gratification at the receipt of expressions of appreciation from engineers who were not only provided with employment during this trying period, but were enabled to utilize their ability in their chosen profession for the accomplishment of projects of lasting value to the nation.

Always modest and unassuming, Admiral Patton was a man of high ideals and integrity. In addition to being an able engineer and executive, he had to a marked degree the qualities which brought him the high esteem and affection of all who knew him. His career is admirably epitomized in the following tribute by Secretary of Commerce Daniel C. Roper:

"In the death of Admiral Patton the Government has lost one of its most capable officials and the engineering profession one of its outstanding leaders. He was held in the highest esteem by his associates and by Members of, and Committees in, the Congress with whom he came in contact, and was recognized as an authority in his work throughout the world. The Coast and Geodetic Survey over which he has been the head for 8½ years is one of the most efficient and progressive bureaus of our Government. Devotion to service by men of the character, integrity and standing of Admiral Patton gives a new assurance to American citizenship; it gives us greater confidence in the future of our country. We grieve over his passing, but we are thankful for his contribution to the service of the Department of Commerce and to the nation."

Admiral Patton was a Past-President of the Washington Society of Engineers; Life Trustee of the National Geographic Society; Trustee of the Woods Hole Oceanographic Institute; and a member of the National Research Council, Association of American Geographers, American Geophysical Union, and the American Astronomical Society. He was also a member of the Cosmos Club, of Washington. He was buried at Arlington National Cemetery with full military honors.

He was married on November 7, 1912, to Virginia Mitchell, of Seattle, Wash., who survives him. He also left a son, Raymond S. Patton; two daughters, Helen M. and Virginia M. Patton; his mother, Mrs. Oliver Patton; a sister, Mrs. J. C. Custenborder; and a brother, Paul C. Patton.

Admiral Patton was elected a Member of the American Society of Civil Engineers on July 11, 1921.

CARROLL PAUL, M. Am. Soc. C. E.[1]

DIED MAY 23, 1937

Carroll Paul was born on May 5, 1882, in Tokyo, Japan, the son of Henry Martyn Paul and Augusta Anna (Gray) Paul. Both parents came of old American stock. His father was descended from that Richard Paul who settled in Taunton, Mass., in 1636, and his mother traced her descent from Peregrine White of the *Mayflower*.

Henry Martyn Paul was graduated from Dartmouth College, at Hanover, N. H., in 1873, and did brilliant post-graduate work in astronomy under the late Professor Charles A. Young, who, later, recommended him for the position of Professor of Astronomy with the University of Tokyo, in Japan, when it was established in 1880. Henry Paul remained in Japan three years, and it was during this time that Carroll Paul, his only child, was born.

In 1884, upon returning to the United States, Professor Paul held a position in the Naval Observatory, at Washington, D. C. It was in the excellent public schools of this city that his son prepared for college. He entered Dartmouth in the Class of 1903, and, at the age of 21, was graduated with the degree of Bachelor of Science. The following year the Thayer School conferred on him the degree of Civil Engineer. While in college he became a member of Phi Delta Theta Fraternity.

---

[1] Memoir prepared in the Longyear Office, Assisted by F. P. Burrall, President of the Longyear Corporations, Marquette, Mich.

In 1904, Mr. Paul entered the United States Reclamation Service, first as Engineering Aid, doing instrument work on the Roosevelt Dam, in Arizona; and then, in 1906, he was sent to the North Platte Project, in Nebraska, where many kinds of office work, such as monthly estimates, computation of costs, design of concrete drops in lateral canals, determination of irrigable lands, etc., were required of him in his capacity of Assistant to the Engineer in Charge of the Distribution System.

In August, 1907, as the result of a competitive examination in which he stood first, he was appointed Assistant Civil Engineer, U. S. Navy, with the rank of Ensign. He was then assigned to duty at the General Electric Company, in Schenectady, N. Y., for the purpose of making tests of electrical machinery for the Navy. In July, 1909, he was transferred to the Bureau of Yards and Docks, at Washington, where, under the Chief of Bureau, he had charge of the Power Plant Section, which handles all plans for operation, repair, extension, and new construction of central power plants in all U. S. Navy Yards and Naval Stations.

In September, 1910, Mr. Paul reported for duty at the Navy Yard, in Norfolk, Va., where, as Assistant to the Public Works Officer, he had charge of the general maintenance and repair of public works at the Yard.

In 1911, shortly after his marriage on March 25, to Helen Longyear, of Marquette, Mich., he was ordered to the Naval Station at Olongapo, in the Philippine Islands, where he acted as Public Works Officer in charge of all maintenance and repair, and, as such, served as a member of the Board for Special Investigation of the Condition of the Floating Dry Dock *Dewey*, which sank one night at its mooring in Subig Bay, apparently without cause. In August, 1911, he was raised to the rank of Lieutenant (Junior Grade).

In November, 1912, he was transferred from Olongapo to the Naval Station at Cavite, Philippine Islands, where he had charge of all public works; this included under-water repairs to a Marine Railway, where inspection had to be made in diving helmet and bathing suit.

At the expiration of his tour of duty in the tropics, Lieutenant and Mrs. Paul returned to the United States by way of India, Egypt, and Europe, using, in this way, leave accumulated during their long absence from home.

Lieutenant Paul, upon his return in September, 1913, was ordered to the Philadelphia (Pa.) Navy Yard as Senior Assistant to the Public Works Officer, who was often called away on other duty, leaving everything in charge of his Senior Assistant. Here, among other things, the work included the designing of ship-building ways, under the general supervision of the Public Works Officer.

In April, 1914, Mr. Paul was commissioned a Lieutenant. The following year he was sent to the Naval Station, at New Orleans, La., where he was in full charge of all public works. He also acted as Senior Assistant to the

Industrial Manager who had charge of all the other operations of the Station, except those of military administration.

During his tour of duty here, in February, 1916, a tropical hurricane came up from Cuba, destroying much shipping along the Mississippi River and jeopardizing a floating dry dock belonging to the Navy Yard. It was a desperate all-night battle to keep the unwieldy structure from breaking loose and smashing its way down river through the anchored shipping, but finally Lieutenant Paul and his men succeeded in getting it under control, saving not only the dry dock, but also the two ships laid up for repairs inside it.

In October, 1916, Lieutenant Paul reported for duty at the Navy Yard in Boston, Mass., but a month later he was sent to emergency duty at the Naval Training Sation, Great Lakes, Ill., to take over work on the building and testing of a mechanical filter plant for the Station.

This work completed, he returned to Boston just before the declaration of war with Germany in April, 1917, and was sent forthwith to Guam, in the center of the Pacific, to build a radio station 600 ft. high. Messages from Nauen, in Germany, were picked up by this sation—at that time considered a remarkable achievement.

In July, 1917, he was made Lieutenant-Commander, and upon his return to the United States in 1919, he went to Yorktown, Va., where he assumed charge of all work at the Navy Mine Depot, the Naval Fuel Oil Station, and the Naval Flying Field—a triple job, executed under trying post-war conditions.

From there, in January, 1922, he was transferred to Parris Island, S. C., as Public Works Officer for the Marine Barracks; in October of that year, following the death of his father-in-law, he resigned from the Navy to become Executor and Trustee of the Estate of John M. Longyear, of Marquette.

Three years later, on October 20, 1925, he joined the Naval Reserve with the rank of Lieutenant-Commander (CEC), which was his status at the time of his death.

With the change to civilian life Mr. Paul stepped into a different existence. His work, which up to that time had been of a more or less standard type, now became far more complex, a kind of "mental engineering," dealing with problems that had no ready solution, for the administration of a large property is no easy matter. Much of his work had to do with technical subjects in unfamiliar fields, such as lawsuits, investments, factory management, and mine leases, but for fifteen years he carried this burden without stumbling, and those who have taken it up now realize how much they owe to his keen analytical mind, his foresight, and his good judgment.

On Sunday, May 23, 1937, Mr. Paul rose early to go rifle shooting—a sport in which he took keen delight. He made an excellent score, returned home, and, while dressing for dinner, fell dead. It was with a profound sense of shock that his family and friends learned what had happened, for every one had thought him in the best of health.

In accordance with his express wish, his funeral in Marquette was followed on June 12, by interment of his ashes in the National Cemetery, at Arlington, Va.

Mr. Paul is survived by his widow, Helen Longyear Paul, and by four children, Beatrice, Howard, Philip Martyn, and Judith.

By virtue of his even disposition and kindly nature, Carroll Paul possessed a true flair for making friends, and his great natural gifts found expression in many ways outside his professional work. For years, he was President of the Local Choral Society, and also one of the pillars of the Marquette Music Club. He did much serious work in music, his fine baritone voice showing to special advantage in oratorios such as the "Messiah."

He found diversion in such sports as swimming and sailing and tennis, but the sport that held his deepest interest, and the one in which he excelled, was shooting. In 1924, he shot moose in Ontario, Canada, and, in 1927, he made a trip into the unmapped Peace River country, in Alberta, Canada, to get Rocky Mountain goats and big horn, bringing back by way of trophy, several beautiful heads. He was a member of a Shooting Club, in Louisiana and a Hunting and Fishing Club, in Michigan, and, as his interest in skeet shooting developed, he organized, in 1936, the Marquette Skeet Club of which he was President at the time of his death.

Other organizations to which he belonged were the Rotary Club, the University Club, of Chicago, Ill., the Army and Navy Club, of New York, N. Y., the Congressional Club, of Washington, D. C., and the Huron Mountain Club, of Michigan. He was also a member of the American Society of Naval Engineers, and of the Naval Institute.

Mr. Paul was elected a Member of the American Society of Civil Engineers on July 9, 1923.

FRANKLIN CALHOUN PILLSBURY, M. Am. Soc. C. E.[1]

Died May 15, 1937

Franklin Calhoun Pillsbury, whose career was so closely interwoven with public highway history in Massachusetts, was by his early connection with the State Highway Commission, a pioneer in the development of the modern highway.

Mr. Pillsbury was Project Engineer of the Massachusetts Department of Public Works. He had previously been Construction Engineer, and before that District Engineer of the former Massachusetts Highway Commission, which was the pioneer in American road-building from the time of the old bicycle days, through the automobile era. Previous ideals and methods had to be cast aside, and new plans devised to make a road surface that would withstand rubber-shod fast traffic.

Franklin Calhoun Pillsbury was born on August 13, 1869, at Chicago, Ill., the son of Samuel and Georgiana (Dix) Pillsbury. He came to Massachusetts as a young man. With a talent for art, he began courses of study and later, taught for a time, in the Eric Pape School of Art, in Boston, Mass. His artistic training proved of value to him when he began the study of engineering, and it was a factor in the selection and planning of highway locations. Not a few Massachusetts highways owe their attractiveness to his vision as an artist which instinctively took advantage of local features of the landscape.

---

[1] Memoir prepared by G. H. Delano, Chf. Engr., State Dept. of Public Works, Boston, Mass.

His early technical experience was obtained in the employ of Mr. Ernest W. Bowditch, of Boston, particularly on surveys and various construction works. Subsequently, as Resident Engineer, he had the responsibility of large landscape, sewerage, and water-works projects, which involved numerous incidental structures of various kinds in many localities.

In 1895, he began his service with the Commonwealth of Massachusetts as Resident Engineer with the Massachusetts Highway Commission, shortly after its organization. In the early years of road-building his practical experience was of benefit in presenting to local communities reliable data and methods for building good roads.

Mr. Pillsbury became a Division Engineer in 1896, and from 1896 to 1920, he had charge of the work of the State Highway Commission in Essex, Middlesex, and Suffolk Counties, the eastern half of Worcester County, and the western half of Norfolk County.

In 1920, he was appointed Construction Engineer, and, in 1923, he was made Project Engineer, in charge of all surveys, designs, and estimates of highway costs (except bridges), the selection of locations and highway layouts, and the preparation of contracts and specifications for construction and reconstruction on all highways built by the Department. In this capacity he planned such great roads as the Worcester Turnpike, the Providence Turnpike, the Southwest Connection by-passing the City of Worcester, the highways connecting the East Boston Tunnel with the North Shore Road, Revere Beach Boulevard, and the Newburyport Turnpike, the Concord Road, Northern and Southern Arteries, and the circumferential highway—in fact, every important highway built by the State in recent years.

It was largely due to Mr. Pillsbury's skill and ingenuity that the old macadam road, the best in its day, was transformed into the bituminous macadam, which is still regarded by many as the best type of automobile highway. His invention of the vehicular pressure-spraying machine, and the method for the construction of bituminous macadam road surface, made a great advance in the art of road-building.

Commissioner of Public Works William F. Callahan has stated that:

> "The training which Mr. Pillsbury obtained as the foundation for his great professional work, was gained in practical experience. It is greatly to his credit, that without the advantages of attendance at college or technical school, he was able to develop correct principles of engineering, which, coupled with his unusual ability to visualize, not only the final completed highway but far beyond that and into the future in the selection of routes and trends of traffic, have resulted in a system of highways to meet the great demands of the rapidly growing volume of motor vehicle traffic. It may be said justly that the present great State Highway system is the result of his extraordinary ability and thorough mastery of highway design and location."

Mr. Pillsbury was a member of the Boston Art Club, Boston City Club, Boston Society of Civil Engineers, Massachusetts Highway Association, the American Road Builders Association, and the Massachusetts State Engineers Association.

He was married on January 14, 1897, to Bessie Wentworth, the daughter of the late Dr. Walter Wentworth, of Pittsfield, Mass. Mrs. Pillsbury died on August 20, 1932. He is survived by two sons, Samuel W. Pillsbury who lives at Saranac Lake, N. Y., and Franklin C. Pillsbury, Jr., of Pittsfield, Mass.

Mr. Pillsbury was elected a Member of the American Society of Civil Engineers on August 31, 1909.

CLARENCE DuBOIS POLLOCK, M. Am. Soc. C. E.[1]

DIED APRIL 30, 1937

Clarence DuBois Pollock was born in Washington, D. C., October 17, 1871, the son of Edie Stewart Pollock and Sallie (DuBois) Pollock. Following graduation from High School, in Washington, D. C., he entered the Massachusetts Institute of Technology, at Boston, Mass., from which he was graduated in 1894 with the degree of Bachelor of Science in Civil Engineering.

During his last two summer vacations Mr. Pollock was employed as Inspector of Sewers in Newton, Mass., and as Instrumentman on surveys along the coast of Maine for the United States Light House Establishment. Immediately following his graduation from college he was for six months Chief of Party on the construction of the Commonwealth Avenue extension through the Newtons (then called Newton Central Boulevard), under the late Henry D. Woods, M. Am. Soc. C. E., City Engineer.

In January, 1895, he came to New York City (where he spent most of the remainder of his life) as Assistant to the late Col. George E. Waring, Jr., at that time Commissioner of Street Cleaning of New York, testing garbage reduction, incineration, and snow-melting machinery. In July, 1895, Mr. Pollock became Assistant Engineer in the Bureau of Street Construction and Maintenance, Department of City Works, Brooklyn, N. Y. When that city became the Borough of Brooklyn of Greater New York he was made Assistant Engineer of the Department of Highways of that Borough, and was engaged in street paving, drainage, utility conduits, street railway reconstruction, etc.

From May, 1900, to March, 1902, with the title of Senior Assistant Engineer of Sewer Division, he was in charge of construction during the rebuilding of the sewers in connection with the building of the first subway (Lafayette Street, Fourth Avenue, 42d Street, and Broadway), with Calvin W. Hendrick, Engineer of Sewers of the New York Rapid Transit Railroad Commission. For the following ten years he served as Principal Assistant Engineer of

---

[1] Memoir prepared by A. Prescott Folwell, M. Am. Soc. C. E.

Highways, in charge of paving construction, first in the Borough of Brooklyn, then in Manhattan Borough, and during the last two years, he was Acting Engineer in Charge of the Bureau.

In 1912, Mr. Pollock was employed by the Cuban Government as Chief Engineer of Pavement Construction in Havana. In the latter part of 1913, he returned to the United States as Consultant to the City of San Antonio, Tex., on street widening and paving under a $4 500 000 bond issue.

From July, 1914, until his death, Mr. Pollock conducted a private engineering practice at 15 Park Row, New York City, serving both municipalities and private corporations as Consulting Engineer on construction, litigation, appraisals, arbitrations, etc. During the World War he had charge, as Project Engineer, of three housing projects for the United States Housing Corporation, and one (at Groton, Conn.) for the United States Shipping Board, which included the construction of all the utilities—water supply, gas, electricity, sewerage, and paving. In 1929 and 1930, he made an engineering investigation of, and report on, the paving and highway work done in Cook County, Illinois, under a $24 500 000 bond issue; and was one of a board of three engineers appointed by Mayor Peters, of Boston, Mass., to conduct a paving investigation. For about fifteen years he was Consulting Engineer of the Granite Paving Block Association. From 1916 to 1921, inclusive, he was Senior Member of the firm of Pollock and Taber.

At the time of his death Mr. Pollock had supervision, as Chief Resident Engineer Inspector for the Public Works Administration, in New York City, of work valued at $18 000 000, including incinerators, sewers, grade crossing, bridges, court houses, jails, etc.

For many years he had been a regular or occasional Lecturer on Paving at several engineering schools, including the Massachusetts Institute of Technology, Johns Hopkins University, Dartmouth College, and the Universities of Wisconsin, Michigan, Ohio, and Chicago.

He was active in many technical societies, including the American Society for Testing Materials, Permanent International Association of Road Congresses, National Conference on City Planning, American Society of Municipal Engineers (of which he was a Director), Brooklyn Engineers Club (of which he was a Charter Member and Past-President), Technology Club of New York, Municipal Engineers Club (of which he was Secretary for several years), and one of the Founders and Past-President of the Technology Alumni Society. For several years he was a Trustee and Financial Secretary of the Bedford Presbyterian Church, in Brooklyn, N. Y.

It is for himself rather than for his professional accomplishments and services that those who knew him best will remember him most. He always saw the best in any one and made allowances for less admirable qualities which could not be ignored. A contractor once said: "I would not think of putting one over on Pollock—I would hate to hurt his feelings", which illustrates the effect of his lovable disposition on even the most "hard boiled." Those under him—assistants, foremen, and laborers—were more than friendly to him, for they knew that he was their friend. Nothing pleased him so much as giving pleasure to others; no trouble was too great if it would do this.

He was married in October, 1896, to Frances Brown, of Boston, Mass., who survives him, as does also a sister, Mrs. Gillett Wynkoop, of Princeton, N. J.

Mr. Pollock was elected an Associate Member of the American Society of Civil Engineers on January 8, 1902, and a Member on April 4, 1905.

HENRY IRWIN RANDALL, M. Am. Soc. C. E.[1]

DIED DECEMBER 29, 1937

Henry Irwin Randall was born at Pownal, Me., on August 20, 1863, the son of William and Helen (Sylvester) Randall. He was educated at the University of California, at Berkeley, Calif., and was graduated from its College of Civil Engineering in 1887.

Mr. Randall entered the employ of the Southern Pacific Company in July, 1887, and from that date until November, 1890, he was engaged on railroad location, construction, and maintenance of the lines of the Company.

From November, 1890, when he left the service of the Southern Pacific Company, until July, 1895, Mr. Randall was employed as Instructor in the College of Civil Engineering of the University of California, and from this latter date until July, 1903, he served as Assistant Professor. During many vacations and also during a short leave of absence from his college teaching, he was engaged by the Southern Pacific Company on railroad location, construction, and maintenance work.

In July, 1903, after resigning his Assistant Professorship at the University of California, Mr. Randall again entered the service of the Southern Pacific Company, in the Engineering Department, as Assistant Engineer, being employed principally on railroad location, construction, and on special work, under the direction of the Company's Chief Engineer, and remained there until December, 1914. During this period, Mr. Randall was engaged on difficult mountain railroad location on sections of the railroad between San Diego and the Imperial Valley, California.

From December, 1914, to January, 1916, Mr. Randall was engaged in private practice; and from January, 1916, until July, 1921, he again was engaged in the service of the Southern Pacific Company, this time as Assistant Engineer in connection with railroad construction and valuation work.

After he left the service of the Southern Pacific Company in July, 1921, and until the time of his death, he did not engage in any professional activities, except for the period from October 3, 1925, to January 15, 1926, when he was again called back by the Railroad Company for some special work on railroad valuation work.

---

[1] Memoir prepared by W. H. Kirkbride, M. Am. Soc. C. E.

Mr. Randall had a high sense of responsibility and devotion to duty, and all work entrusted to him was completed with painstaking care. He was a skillful and accomplished engineer and a man of high principles and integrity.

He was a member of Durant Lodge, Free and Accepted Masons, Berkeley Commandery, Knights Templar, and the First Congregational Church, of Berkeley.

Mr. Randall was granted a life membership in the Society in 1934, having paid dues as a Corporate Member for thirty-five years.

He is survived by his widow, Mrs. Gertrude L. Randall; two sons, Richard Ray Randall, and Winslow H. Randall; and a daughter, Elizabeth Randall.

Mr. Randall was elected a Member of the American Society of Civil Engineers on February 7, 1906.

ARTHUR LOWRIE REEDER, M. Am. Soc. C. E.[1]

DIED MAY 24, 1937

Arthur Lowrie Reeder, the youngest of four sons, was born on June 8, 1879, at Camden, N. J. His ancestors were of English and Dutch stock—with a trace of Scotch. His father's great-great-great-grandfather, John Reeder, came from England to Salem, Mass., in 1652. His grandmother's great-great-grandfather came from England to Bristol, Pa., in 1705, and bought a farm of 475 acres in the vicinity. His mother was the great-granddaughter of Dr. Isaac Harris, of Southern New Jersey, who was a surgeon on General Washington's Staff during the Revolutionary War. She was also descended from Cornelius Van Nieukirk, of Holland, whose son came to this country in 1659.

One of Arthur Reeder's ancestors, when only two years old, was almost burned at the stake by Indians. Held in his mother's arms, he was saved by a rescue party before any serious damage had been done. Another ancestor ran an early ferry-boat between Brooklyn, N. Y., and New York, N. Y., near the site of the present Brooklyn Bridge.

Silas Andrews Reeder, his father, a graduate of the University of Pennsylvania Medical School, at Philadelphia, Pa., was a Surgeon in the United States Navy throughout the Civil War, being attached to various vessels of the Key West Squadron, engaged in the blockade of Mobile, Ala., and other Southern ports.

Arthur Lowrie Reeder obtained his education in the Central High School, of Philadelphia, and the University of Pennsylvania, where he obtained the degree of Bachelor of Science in Electrical Engineering, in June, 1900. He began work immediately with the New York Shipbuilding Company, of Camden, as a Special Apprentice. The following year he went to the William Cramp and Sons' Ship and Engine Building Company, of Philadelphia as a helper on installation of auxiliary machinery in ships.

---

[1] Memoir prepared by William C. Reeder, M. Am. Soc. C. E.

In May, 1902, after a few months with the Baldwin Locomotive Works, he entered the service of the Filtration Bureau, of Philadelphia, on the design and construction of a $28 000 000 improvement to the Water System, including five filter plants, pumping stations, conduits, pipe lines, reservoirs, etc. He also had charge of the design, specifications, construction, and maintenance of all electrical work, and, later, represented the Water Bureau in an electrolysis survey of all water pipes in the City's system. This engagement lasted seven years.

After a year as an Instructor of Mathematics at Temple University, in Philadelphia, Mr. Reeder began, in 1910, a 5-yr engagement with the Water Department of the City of Baltimore, Md., as Designing Engineer, Chief Draftsman, and Principal Assistant Engineer on a $5 000 000 water supply improvement, including the design and construction of a dam, pumping station, and a 128 000 000-gal mechanical filter plant.

From March, 1916, to May, 1918, Mr. Reeder was, successively, Assistant Engineer with Hill and Ferguson, of New York, N. Y., on water supply, water purification, sewage treatment, etc.; with the late James H. Fuertes, M. Am. Soc. C. E., of New York City, on city planning, water supply, and design of sewage treatment plants; and with Day and Zimmerman, Incorporated, of New York City, on appraisal work.

For the next two years, he was with the Pennsylvania Department of Health, in the Design and Construction Section of the Engineering Division, as Assistant Engineer and Section Chief on investigations, plans, specifications, and supervision of construction, for water supply, sewage treatment plants, incinerators, and the preliminary design of two large hospitals for contagious diseases.

The following year Mr. Reeder was engaged with the Division of Water, of the City of Cleveland, Ohio, as Senior Assistant Engineer on underpinning, design of filter plants, and studies of chemical solutions.

From June, 1921, to March, 1924, Mr. Reeder began the first of a series of three engagements with the Bureau of Water, at Reading, Pa., at this time making a thorough study of the existing water facilities of the city and formulating a comprehensive plan for the extension and improvement of the water supply, at an estimated cost of $7 600 000.

During the remainder of 1924 and 1925, Mr. Reeder was with Gannett, Seelye and Fleming, Engineers, Incorporated, of Harrisburg, Pa., in charge of all designs and specifications for dams, filter plants, pumping stations, and sewerage. In 1926 and 1927, he was again with the Reading Water Bureau as Engineer in charge of the Improvement Division on the preparation of a reservoir site, the design and construction of a dam and reinforced concrete highway arch bridge, and the preliminary design of a 42 000 000-gal mechanical filter plant.

In 1928, Mr. Reeder was with the Mahoning Valley Sanitary District, of Youngstown, Ohio, in charge of all designs for a new water system for

Youngstown and Niles, Ohio, including force mains, clear-water reservoir, electric pumping station, and a 42 000 000-gal water purification and softening plant, the total cost of which was estimated at $9 150 000. From the fall of 1930 to March, 1932, he was again in Youngstown continuing this improvement. During 1929 and early in 1930, Mr. Reeder was with H. Burdett Cleveland, M. Am. Soc. C. E., of New York City, as Principal Assistant Engineer on the construction of a trunk sanitary sewer and treatment plant and the design of incinerator and water supply improvements.

From April, 1932, to December, 1935, he returned for his third engagement with the Reading Water Bureau, as Engineer in charge of the Design Division, on active resumption of the improvement work. This included the plans and specifications for twenty-three contracts for the construction of a pressure tunnel, two clear-water reservoirs, and the first unit consisting of one-half of the ultimate 42 000 000-gal mechanical filter plant.

The year 1936 was spent in extensive genealogical research. At the beginning of 1937, Mr. Reeder began an engagement with Morrell Vrooman, Incorporated, and was designing a water filtration system for Gloversville, N. Y., at the time of his sudden death.

His large-scale water supply improvements included the design, construction, and repair of eighteen water purification plants, having a combined daily capacity exceeding 970 000 000 gal.

Mr. Reeder was quiet and unassuming, but had a keen sense of humor. His reaction to casual events showed a mind acutely alive to the ridiculous. His wit was never unkind nor at the expense of others. He had many friends and no enemies. His engineering work was most painstaking and accurate, and he was punctilious in maintaining the highest ethical standards.

He was a member of the American Water Works Association, the Pennsylvania Water Works Operators' Association, and the National Geographic Society. He was also a member of the Presbyterian Church.

He was married on June 8, 1904, to Annie A. Helffrich, who died in Reading, Pa., in November, 1934. They had no children. He is survived by three older brothers, Franklin H. Reeder, William C. Reeder, M. Am. Soc. C. E., and Robert P. Reeder.

Mr. Reeder was elected a Member of the American Society of Civil Engineers on August 29, 1927.

THERON MONROE RIPLEY, M. Am. Soc. C. E.[1]

DIED NOVEMBER 30, 1936

Theron Monroe Ripley was born at Macedon, Wayne County, N. Y., on September 28, 1868, the son of Theron Powell Ripley and Anne (Norton) Ripley. His career includes participation in two wars, construction of bridges and hydro-electric plants, rehabilitation of canals, and the building of main-line highways.

---

[1] Memoir prepared by a Committee of the Buffalo, N. Y., Section, consisting of John H. Feigel, Assoc. M. Am. Soc. C. E., and George S. Minniss, and George F. Unger, Members, Am. Soc. C. E.

His college training was obtained at Marietta College, in Marietta, Ohio, from which he was graduated in the Arts Course and, having shown a special aptitude for mathematics, he obtained a position with the Montana Railroad Company at Helena, Mont., in September, 1893, and was connected with the running of sixty miles of preliminary surveys on railroad lines through unusually difficult topography.

Young Ripley then obtained a position with the Montana Power Company making surveys for a new hydro-electric plant on the Missouri River, on which he later served as Resident Engineer during construction.

In April, 1898, with the true patriotic fervor which he possessed, he left Montana to participate in the Spanish-American War, first as a Sergeant in the First Montana Volunteer Infantry, seeing service in the United States and, finally, in Manila, Philippine Islands. At the conclusion of the war with Spain, Mr. Ripley entered the employ of the Philippine Commission and served until 1901 as Superintendent of Parks for the City of Manila.

On his return to the United States in 1901, he became Supervising Engineer for the Ohio Bridge and Ferry Company on the construction of a new bridge across the Ohio River, at Marietta, Ohio. At that time he made a special study of the Ohio Canal and for a year was Chairman of the Legislative Committee of the Ohio Canal Association.

From 1903 to late in 1905, he carried on a private practice as a Consulting Engineer, at Marietta, during which time he made surveys for electric railroad lines and numerous other utilities. He also designed and built the sewage disposal plant for Washington County, Ohio.

Mr. Ripley returned to New York State in 1905, and served, successively, as Assistant, Senior Assistant, and Resident Engineer on the Barge Canal in New York State. During this time he designed locks, dams, prisms, retaining walls, etc., and collaborated in re-writing the Barge Canal Specifications; he made an inspection of the progress work on the Mohawk River, and, later, had charge of work on the Oswego River amounting to $5 000 000, including new and varied types of construction, and the installation of several Tainter gates.

In 1913, he became Division Engineer in the New York State Highway Department and had charge of the Watertown, N. Y., Office, with the supervision of surveys, design, and construction, as well as maintenance of that important construction division with its modern, improved roads through the Adirondack Mountains.

At the entrance of the United States into the World War, Mr. Ripley was commissioned a Major of the Corps of Engineers, U. S. Army. He reported for active duty on December 28, 1917, at Camp Lee, in Petersburg, Va., and on January 5, 1918, was made Chief Engineer at Camp Abraham Eustis, near Newport News, Va., and very shortly thereafter was made Construction Quartermaster at Chickamauga Park, Georgia, which included Camp Forest, Camp Greenleaf, Camp Oglethorpe, as well as Base Hospital No. 14 and Prison Barracks.

At the conclusion of the war the necessity for the settlement of claims, and other business connected with the Chickamauga Camp, held Major Ripley in service until June 24, 1919. At the termination of his military service he returned to the New York State Highway Department as Division Engineer at Watertown, and later, at Hornell, N. Y.

Early in 1921 he was made District Engineer of the New York Department of Public Works, in charge of surveys, design, construction, and maintenance of highways, maintenance of the Barge Canal, 3 000 miles of highways, and 20 miles of canal and terminals, with headquarters at Fulton, N. Y. In 1925, he was placed in charge of the Western Division, with headquarters in Buffalo, N. Y.

In May, 1926, Major Ripley resigned from his position with the State to accept an appointment by the Erie County Board of Supervisors as Chief Engineer of the Greater Motorways Project in the Erie County Highway Department. As Chief Engineer of this project he built a system of wide highways in the towns adjoining the City of Buffalo that involved more than $25 000 000 in construction cost. He initiated and had charge of 1 200 sq miles of aerial surveys and mapping of Erie County, New York.

The Greater Motorways System included the construction of Sheridan Drive in the Towns of Tonawanda and Amherst, and the Southwestern Boulevard through West Seneca, Hamburg, and several other Western New York towns.

In January, 1931, the task of completing the Greater Motorways of Erie County having been accomplished, Major Ripley retired from public service and established a private consulting engineering practice which he carried on until the time of his fatal illness. His practice consisted of appearances before the Public Service Commission of New York State as an expert on grade separation and grade-crossing elimination, as well as expert testimony before the New York State Court of Claims.

He also took a deep interest in the improvement of the New York State Barge Canal and, by his intense study of the St. Lawrence Waterway Project, he became one of the best informed engineers in the East of this project. During the three or four years preceding his death, he was Chairman of the Canals and Waterways Committee of the Buffalo Section of the Society and wrote exhaustively on some of the phases of the St. Lawrence Waterway.

On May 8, 1902, Major Ripley was married to Edith Mills, of Marietta, Ohio and the delightful companionship of these two former students at Marietta College continued during the Major's lifetime. His widow survives him, as does also a son, Mills N. Ripley, and a daughter, Mrs. Edwin F. Cellette.

Major Ripley was an active member of many professional and social organizations, among them being the Buffalo City Planning Association, Buffalo Chamber of Commerce, Liscom-Seyburn Post, Spanish-American War Veterans, American Legion, American Society of Military Engineers, Buffalo Athletic Club, Rotary Club, of Watertown, N. Y., Torch Club, of Buffalo, and the Delta Upsilon Fraternity.

As an indication of Major Ripley's patriotism he held, until the time of his death, a commission as Major in the Engineers' Reserve Corps in the United States Army.

He was a member of the First Presbyterian Church, of Buffalo. His funeral was held from Forest Lawn Chapel and conducted by his dear friend, Dr. Ralph B. Hindman.

Major Ripley was elected an Associate Member of the American Society of Civil Engineers on November 6, 1901, and a Member on February 28, 1911.

WILLIAM KERPER RUNYON, M. Am. Soc. C. E.[1]

Died February 28, 1938

Few men are privileged, during their lifetime, to travel as "Bill" Runyon did, to many of the remote and little known corners of the earth, there to find important work for their minds and hands to do, strange sights for their eyes to see, and interesting friends to share their joys and sorrows.

William Kerper Runyon was born in Newark, N. J., on January 11, 1877, the son of Enos and Rose (Kerper) Runyon. Both parents were descended from early American families, and were natives of Rahway, N. J., and Reading, Pa., respectively.

Mr. Runyon attended the Newark Academy and the Newark High School, from which he was graduated at the age of fifteen. He entered Lafayette College, at Easton, Pa., from which he was graduated in Civil Engineering in 1896, and received his Master's Degree in 1899.

Upon leaving college in 1896, he started his professional career as a Rodman for the Erie Railroad Company in New Jersey. He resigned from this position in 1898 to enlist for the Spanish-American War, during which he served as a private in the 2d New Jersey Volunteer Infantry.

Following the war, he obtained his Master's Degree and, from 1899 to 1901, held various positions as Rodman and Chief of Party on railroad valuation and construction work with the New Jersey State Board of Assessors, the North Jersey Title Guarantee Company, and the West Virginia Short Line Railroad Company.

November, 1901, found him in Cuba, where he was employed as Resident Engineer on railroad construction for the Cuba Company, at Camaguey, Cuba. Following this engagement he returned to the United States and the Erie Railroad Company for a few months, as Transitman.

The lure of foreign places was strong, however, and in October, 1902, he obtained an appointment as one of three American engineers employed by the America-China Development Company on the location and construction of the Canton-Hankow Railroad, with headquarters in Canton, China. His duties on this project carried him far into the interior of China, to provinces which had never before been visited by white men. It is interesting to read his accounts of experiences among the ignorant and poverty stricken people of this country, who regarded his every movement with curiosity, wonder, and trepidation. In recognition of his outstanding service on this project, he was made a " red button " Mandarin, and was supplied with interpreters, soldiers, and servants on all his trips.

---

[1] Memoir prepared by W. F. Foster, M. Am. Soc. C. E.

While engaged on this work, he found himself at times regarded by people of the country as a benevolent foreign god, and, at other times, the object of rifle fire—a man with a price upon his head. Undaunted, he quietly and unswervingly carried to completion the location and construction of his division of the great railroad, accomplishing delicate diplomatic missions with high governmental officials and solving technical problems with equal facility. It was during this engagement that Mr. Runyon first became acquainted with Herbert Hoover, Hon. M. Am. Soc. C. E., for whom he always maintained the highest regard.

Leaving China in November, 1904, Mr. Runyon went to Tampico, Tamps., Mexico, where he made a survey of the asphalt deposits for the Pan-American Company. One year later, in November, 1905, he became Resident Engineer for the Cuba Eastern Railroad, at Guantanamo.

From July, 1906, to September, 1907, he was employed by the Bolivia Railway Company as Locating Engineer, with headquarters in La Paz, Bolivia, but was forced to leave when he contracted pneumonia while working in mountainous territory at an altitude of 13 000 ft above sea level.

In September, 1907, he was appointed a Division Engineer on the famous Madeira-Mamore Railway, at Porto Velho, Brazil. It is said of the construction of this railroad that "a man was buried with every tie." Repeated attacks of jungle fever finally forced Mr. Runyon to leave the project after two and one-half years of service, at which time he and the Surgeon General were the oldest men in point of service remaining on the project.

In June, 1910, he had recovered sufficiently from this experience to take a position as Assistant Engineer engaged in the physical valuation of the property of the New York Central Railroad Company, for the State of Massachusetts.

Returning to South America in March, 1911, Mr. Runyon was engaged by the Government of Peru and the Eddy Peruvian Company as Assistant Chief Engineer and, later, as Chief Engineer in the making of preliminary surveys and estimates for the construction of the Amazon Pacific Railroad, the Ucayali Railroad, and the Huancayo-Ayacucho Railroad, in that country.

Mr. Runyon next operated a copper mine at Moquequa, Peru, as General Manager and part owner, but disposed of his interests when the United States entered the World War.

Returning to this country, he served as Office Engineer in the Office of the Chief of Engineers, War Department, Washington, D. C., where he was principally engaged in the distribution of materials for military railways until the close of the war, and thereafter in the inventory and sale of this equipment.

Soon after coming to Washington, he was married to Minerva M. Byrne, in December, 1918, who passed away on December 27, 1931.

Upon the completion of his work with the War Department in August, 1920, Mr. Runyon returned to Peru as Chief of the Technical Division of Wessel, Duval and Company, importers and exporters of automobiles, tractors, trucks, and machinery, with headquarters at Lima.

In January, 1924, Mr. Runyon went to California and in August of that year was engaged as a Civil Engineer in the office of the Los Angeles County Surveyor. He became Deputy County Surveyor in charge of the Sanitary Sewer Permit Division, which was established under his direction. He made many friends among engineers, contractors, and property owners who appreciated the ability, tact, and courtesy with which this Division issued and inspected more than 30 000 permits for sewer connections during the fourteen years that preceded his death.

During this period he also supervised the preparation of sewer records and maps of more than 810 miles of sanitary sewers constructed under the supervision of the County Surveyor, and computed the quantities upon which payment to contractors was made for this work.

Mr. Runyon was a member of the Phi Kappa Psi Fraternity, and the Bone and Key, when in college, and remained an active member of his Alumni group. He was a member of South Pasadena Lodge of Masons, the Royal Arch, Knights Templar, a Thirty-second Degree Mason, and a member of the Al Malaikah Shrine, at Los Angeles, Calif.

He is survived by his widow, Mrs. Margaret Francis Runyon, to whom he was married in August, 1932.

Those of his friends who knew him best will always remember his quiet, kindly disposition, his courtesy and tact, his unswerving loyalty, his ready smile, and cheerful disposition.

At the insistence of friends, Mr. Runyon wrote a number of sparkling articles on his experiences in China, which were published and enjoyed by his many co-workers and others. Those stories revealed how greatly he enjoyed his life in all its fullness, and furnished some conception of the manner in which American engineers became known throughout the world as ambassadors of peace and good will.

Mr. Runyon was elected a Junior of the American Society of Civil Engineers on April 5, 1898; an Associate Member on October 5, 1904; and a Member on May 8, 1922.

HIRAM NEWTON SAVAGE, M. Am. Soc. C. E.[1]

DIED JUNE 24, 1934

Hiram Newton Savage was born in Lancaster, N. H., on October 6, 1861, the son of Hazen Nelson and Laura Ann (Newton) Savage. He was the son of a farmer. After his public school education, Mr. Savage worked his way through the New Hampshire College of Agriculture and the Mechanic Arts, at Durham, N. H., from which he was graduated in 1887, with the degree of Bachelor of Science. In 1891, he was graduated from the Thayer School of Civil Engineering, of Dartmouth College, with the degree of Civil Engineer. In 1913, the University of New Hampshire conferred upon him the honorary degree of Doctor of Science.

---

[1] Memoir prepared by Charles P. Williams, M. Am. Soc. C. E.

In 1888, Mr. Savage was Assistant Engineer, and, later, Resident Engineer, of the East Tennessee and Georgia Railway, the Nashville and Tellico Railway, and the Athens (Tenn.) Improvement Company. From May to July, 1889, he served as Assistant Engineer of the Hydraulic Mining Company, in the San Pedro Mining District, New Mexico, and from July, 1889, to April, 1890, he was Chief Engineer of that Company and of the Rio Grande Water Company, in New Mexico, in charge of a survey of the Ortiz, San Pedro, and Tejon Grants, embracing 100 000 acres; placer-mine prospecting and locations; ditch location and construction; and preliminary location and estimate for a pipe line, 58 miles in length. From April to September, 1890, he was Engineer of "Billings Park", White River Junction, Vermont. In September of that year he located an extension of the sewerage system of West Randolph, Vt.

After his graduation from the Thayer School of Civil Engineering in 1891, Mr. Savage went to Southern California, and was employed by the San Diego Land and Town Company, of National City, Calif., as Chief Engineer, in charge of the construction of the Sweetwater Dam and Distribution System that was to be used to furnish irrigation and domestic supply. His work included the construction and reconstruction, operation, and maintenance of the System; the partition and subdivision of 40 000 acres of land; the location, construction, and maintenance of the National City and Otay Railway; and the construction of Sweetwater Park and Race Track, at National City.

In 1895, Mr. Savage became Consulting Engineer to the Southern California Mountain Water Company, in connection with the Morena, Upper Otay, and Lower Otay Dams, and the water-carrying system to San Diego, Calif.

From 1898 to 1903, he was Consulting Engineer for the San Diego and Cuyamaca Railway Company, the San Diego and La Jolla Railway Company, the Coronado Beach Railway Company, the Cuyamaca Water Company, and for the Contractor for the Zuninga Shoals Jetty, in San Diego Harbor, a Government project.

In 1903, Mr. Savage was appointed Consulting Engineer in the United States Reclamation Service, the organization of which had been begun the preceding year, and, from 1905 to 1915, he was Supervising Engineer of the Northern Division of that Service, including the States of Montana, North Dakota, and Wyoming. The District included eleven primary projects: The Huntley, Lower Yellowstone, Sun River, Milk River, St. Mary (storage), Flathead (Indian), Blackfeet (Indian), and Fort Peck (Indian) Projects, in Montana; the Williston and Buford-Trenton Projects, in North Dakota; and the Shoshone Project, in Wyoming; all of which were under construction and operation within the period of his service. He also investigated the irrigation possibilities for about ten secondary projects, with a view to their construction when and if funds were made available. Among the many important structures built on the primary projects were the Shoshone Dam, a concrete arch, 328 ft in height above the foundation, then the highest dam in the world, and the Corbett Tunnel, 11 ft in diameter and 3 miles long. In addition to his work in the Northern Division of the Reclamation Service, Mr. Savage at times served on Consulting Boards relative to the work in other Divisions.

He resigned from the U. S. Reclamation Service in 1915 and, in 1916, became Consulting and Supervising Engineer for the Sweetwater Water Company of California, engaged on the reconstruction and enlargement of the Sweetwater Dam, the spillway and abutments of which had been damaged by the record flood of 1916.

From 1917 to 1923, Mr. Savage was Hydraulic Engineer for the City of San Diego, Calif. He supervised the design and construction of the Barrett and the new Lower Otay Dams, the enlargement and reconstruction of Morena Dam and Spillway, and the extensions to the City's rapid sand filtration plants. During this period, he compiled all known hydrographic and climatological data for San Diego County, made estimates of the future water requirements for the City of San Diego and vicinity, investigated available water resources, and made a plan of future water development for the city and its environs, together with plans and estimates for the dams, reservoirs, carrying systems, and purification plants necessary for accomplishing this program. He made filings of water appropriations and intiated proceedings for the acquisition of the necessary rights of way. Notwithstanding the excellent and valuable work done by Mr. Savage during this engagement, his relations with the City Government of San Diego were not at all agreeable. The City Council was composed largely of politicians, who had little appreciation of his work, and whose actions were governed by political motives, rather than the good of the community. Finally, when attending a meeting of the hostile City Council, he was subjected to a tirade of criticism and abuse, and was informed that his services were terminated. Much to the chagrin of his opponents, who had expected a retort in kind, he replied calmly "very well", and with sedate dignity withdrew from the Council Chamber.

In 1923 and 1924, Mr. Savage made a trip around the world, visiting nineteen foreign countries, including Italy, Egypt, the Sudan, the Holy Land, Java, the Philippine Islands, China, and Japan. A second tour was made in 1924 and 1925. On this tour, he visited Hawaii and twenty foreign countries, including the South Sea Islands, New Zealand, Australia, the Philippine Islands, and India, where he explored the Ganges and Indus River Systems. He visited also Mesopotamia, where he reported to both King Feisal and to the British officials, on the irrigation and drainage requirements for the Government irrigation system at Irak. He traveled overland across the Holy Land, and reported on Zion and National Home movements; inspected the drainage basin in Egypt and the Sudan, traveling southward in Equatorial Africa more than 5 000 miles by railways, water routes, and overland on foot, conveyed by a force of negro porters. He went into Abyssinia, through the Sudan to the Belgian Congo, continuing through Uganda and across Lakes Albert Nyanza, Kioga, and Victoria Nyanza, to the head-waters of the Nile. Continuing southerly he went through Kenya, *via* Nairobi and Tanganyika, to Zanzibar and the Indian Ocean, thence returning by way of the Red Sea to Cairo, where he reported to the late King Fuad I, of Egypt, and to the Government officials of the Sudan, Egypt, and the British Empire, on the irrigation requirements of Egypt and the Sudan, on the water resources and on the control of the Nile, with recommendations to construct a third dam on the Nile at Nag Hamadi, and to increase the height of the Assuan Dam sufficiently to double the present storage capacity.

In 1925 and 1926, Mr. Savage inspected twenty-five National, State, and Corporate irrigation projects, in the western part of the United States and in Alberta, Canada, reporting to President Calvin Coolidge on their administrative, technical, social, and economic conditions and requirements.

In 1926 and 1927, he made a tour of inspection of the majority of the Latin-American Republics in the West Indies, Central America, and South America, going from New York, N. Y., to the West Indies, thence to Central America, through the Panama Canal, along the West Coast of South America, by the Transandine Railway, from Valparaiso, Chile, to Buenos Aires, Argentine Republic, and thence back to New York. Several trips were made into the Andes Mountains. From Buenos Aires he made a trip inland of more than 1 800 miles. From Rio de Janeiro, Brazil, a trip was made into the interior of Brazil, to and down the Alta Parana River, one of the principal tributaries of the Rio de la Plata. On this tour, studies were made of the natural resources of the several countries, with reference to the feasibility of their development and utilization.

In 1927, Mr. Savage again made inspections of the principal irrigation projects in Western United States, reporting thereon to President Coolidge. He also inspected irrigation and hydro-electric projects in Alberta and British Columbia, Canada.

In 1927 and 1928, he made a third trip around the world, visiting Latin-American Republics of South America, thence across South America by the Transandine Railway, across the Atlantic, traveling 4 000 miles in South Africa, from Cape Town to the Belgian Congo, continuing to Mozambique, Tanganyika, and Kenya, across the Indian Ocean, and to the interior of Northeast India, thence to Arabia, Egypt, and the controlling works of the Nile. From here, he went to the Holy Land, thence over Asia Minor to the Black Sea, continuing through Turkey, Greece, Italy, Switzerland, and France to England and Scotland. In these latter countries, he inspected the water supply and work at Manchester, the combined water supply project of Manchester and Liverpool, and the water supply of Glasgow, returning by way of Ireland, thence across the Atlantic to Canada and the United States.

For a time Mr. Savage was associated with Research Service, Inc., of Washington, D. C.

After five years of fruitless endeavor by the City of San Diego, to make some progress in the development of its water resources, within which time the Sutherland Dam was begun and later abandoned, the citizens had become so insistent in demanding the return of Mr. Savage that the City Council deemed it necessary to comply with their demands; accordingly, on July 2, 1928, he again took charge of the Municipal Bureau of Water Development, Operation, and Maintenance. From this time until his death he served the City with zeal and untiring energy. Even during his last sickness, he insisted on being informed daily regarding the progress of the work under his charge.

During this last engagement negotiations and acquisitions of rights of way and water rights progressed as rapidly as economically possible. Arrangement with the Federal Government was made relative to securing, when needed, an additional supply of water from the Colorado River, and plans were developed for works for the conveyance of this supply. The El Capitan Dam was constructed giving the city an additional supply of 10 000 000 gal per day.

Throughout his life Mr. Savage had an uncanny knowledge of human nature and exemplified great fortitude in overcoming obstacles and in pushing work. His ability to find the "ulterior motive", together with his unquestioned honesty of purpose and integrity, made him loved by his friends and hated by those who opposed him.

His motto was "the most good for the greatest number throughout the longest time". Stoical as an Indian, he was never swerved by praise or criticism.

In recognition of the valuable work he had done for the City of San Diego in the development of its water supply, the City Council on July 9, 1934, changed the name of Lower Otay Dam to Savage Dam.

His foresight and ability to anticipate future needs and plan accordingly were remarkable. Sweetwater, Barrett, Morena, El Capitan, and Savage Dams, which will serve the inhabitants of the San Diego area for ages to come, will stand as monuments to his ability as a man and as an engineer.

Mr. Savage was married in December, 1891, to Linna Bell Clough, of New Hampshire, who died in October, 1897. Two daughters were born to them, Lucy Eunice (Mrs. Robert L. Colthart) and Laura Ada (Mrs. Lawrence W. Hoppe). In 1927, Mr. Savage was married to Eugenia Hurlock, of Maryland, who, with his daughters, survives him.

He was a member of the University Club and the Rotary Club of San Diego. He was also a member of the Masonic Order.

Mr. Savage was elected an Associate Member of the American Society of Civil Engineers on March 7, 1894, and a Member on October 7, 1896.

WALTER JUSTIN SHERMAN, M. Am. Soc. C. E.[1]

Died April 15, 1937

Walter Justin Sherman was born at Florence, Ohio, on October 16, 1854, the son of Nathan Gould and Elizabeth (Otis) Sherman, and the grandson of Justin Sherman who settled at Wakeman, Huron County, Ohio, in 1822. He was a lineal descendant of Sarah Mitchell, the sister of an early President of Harvard University, and of Samuel Sherman who settled in Watertown, Mass., in 1634.

After his graduation from Norwalk (Ohio) High School in 1873, Mr. Sherman entered Cornell University, at Ithaca, N. Y., from which he was graduated in 1877, with the degree of Bachelor of Civil Engineering, which later was followed by his Civil Engineering degree. During Mr. Sherman's attendance at Cornell University he was a member of the Delta Kappa Epsilon Fraternity; he was also a member of a famous rowing crew.

Mr. Sherman's graduation was coincident with a great era of steam railroad construction, and, at once, he became Assistant Chief Engineer of the Lake Erie and Louisville Railroad. The following year he was appointed Chief Engineer of the Delphos and Kokomo Railroad and the Delphos, Bluffton and Frankfort Railroad. Then followed these milestones of his railroad and other engineering projects: 1879, Locating Engineer for the Chicago and Atlanta Railroad; 1879–1881, Chief Engineer for the Toledo, Delphos and Burlington Railroad; Chief Engineer for the Dayton and Southeastern Railroad; 1881–1884, Chief Engineer for the Louisville, Evansville and St. Louis Railroad; 1884–1888, Assistant Chief Engineer for the Gulf, Colorado and Santa Fé Railroad; 1889–1890, Chief Engineer for the Dallas, Pacific and Southeastern Railroad, for which Company he built 300 miles of railway in 300 working days; 1890, Chief Engineer for the Dallas (Tex.) Rapid Transit Railroad and the North Dallas Circuit Railroad; 1892–1893, Chief Engineer for the Galveston Construction Company, on the building of the Galveston, Tex., Harbor Works; 1894–1895, Contracting Engineer for the Toledo (Ohio) Bridge Company; and 1896–1897, Chief Engineer for the Wheeling and Lake Erie Railroad. The town of Justin, Tex., was named for Mr. Sherman.

In November, 1896, he formed a partnership with Henry E. Riggs, M. Am. Soc. C. E., under the firm name of The Riggs and Sherman Company, for the general practice of civil engineering. This partnership continued until April 30, 1912, when Mr. Riggs joined the Engineering Faculty of the University of Michigan, at Ann Arbor, Mich. Of this partnership, Professor Riggs states:

"The fact that two men formed an engineering partnership which continued for fifteen years and a half and during that time never had any argument or dispute over matters of policy, questions of design or finances, indicates that their friendship was very close. Sherman was one of the fairest, most honorable men I have ever known."

---

[1] Memoir prepared by the late George Champe, M. Am. Soc. C. E.

Reorganizing under the name of The W. J. Sherman Company, practice was continued until 1927, when, celebrating fifty years of continuous and active practice of civil engineering, Mr. Sherman retired from the profession and devoted his time to personal affairs, studies and writings, and projects in behalf of the Ohio State Archæological and Historical Society and the Historical Society of Northwestern Ohio, of which he was President-Editor at the time of his death. The most beautiful monument erected in the State Park in the Maumee Valley commemorating the Battle of Fallen Timbers, is one of the direct results of his untiring efforts.

Mr. Sherman's important engineering assignments included municipal water-works systems and water purification works, sewerage systems and sewage treatment works, revetment and dock construction, railroad and highway bridges, a fire service pumping station for the City of Toledo, and many other projects.

He was the author of numerous technical papers, including: "The Ohio Centennial Exposition", read before the Michigan Society of Engineers, in 1900; "The Sewers of London", read before the Toledo Society of Engineers; "The Development of a Coal Mine", published in the *Cornell Civil Engineer*, 1907; "The Public Water Supply of the City of Philadelphia", read before the Toledo Society of Engineers; "Water Purification at Fostoria, Ohio", published in *The Southern Engineer*, Atlanta, Ga., 1907; reports on the water supply problems of Salem, Cambridge, Zanesville, Newark, Wellsville, Delaware, and Defiance, Ohio; Muskegon and Adrian, Mich., and many other places; "Valuation of Ann Arbor Water Works, with a View of Municipal Ownership"; "Some Observations on Electric Railways", read before the Michigan Society of Engineers; "The Galveston Harbor Works", read before the St. Louis Engineering Society; "Flood Prevention at Lima and Marietta", read before the Ohio Engineering Society; reports on "The Pollution of Swan Creek and Ottawa River", Toledo, Ohio, and "The Diversion of Swan Creek"; "Should Engineers in the Teaching Profession Engage in Private Practice"; "Old Fort Industry and Miami", published in Van Tassell's "History of the Maumee Valley"; "Fort Industry—an Historical Mystery", published in *Quarterly Bulletin* of the Historical Society of Northwestern Ohio; "Mad Anthony Wayne in the Maumee Valley"; "The Future of the Ohio Canal System"; "The Status of the Engineer under Ohio Laws", "Barge Canals and Canalized Rivers"; "Inland Waterways"; "Underground and Surface Water Supplies"; and "Flood Prevention at Mansfield, Ohio".

Mr. Sherman was a life member of the Ohio Archæological and Historical Society, The Firelands Historical Society, and the Ohio Society of Sons of the American Revolution.

On July 14, 1892, he was united in marriage with Catherine Bowmer, at Cloverport, Ky. Mrs. Sherman survives him with their two daughters, Mrs. Lynn (Margaret B.) Troxel, of Tiffin, Ohio, and Mrs. C. Barnes (Elizabeth M.) Walbridge, of Toledo, and seven grand-children.

It was the writer's privilege to know Mr. Sherman intimately for more than thirty years as professional associate and competitor, fellow club and church member, and neighbor, and to realize that the Engineering Profession has lost an outstanding member. Although he had not been in active practice for a number of years, his interest in engineering had continued unabated until the time of his death.

Mr. Sherman was elected a Member of the American Society of Civil Engineers on March 4, 1909.

JOHN KENNETH WEST SHIBLEY, M. Am. Soc. C. E.[1]

Died May 1, 1937

John Kenneth West Shibley was born on March 17, 1882, in Yorker, Ont., Canada. When he was three years old his parents moved to Colton, Calif., where he attended the public schools. He was graduated from the San Bernardino (Calif.), High School, and, in 1901, entered the University of Southern California, at Los Angeles. In 1903, he transferred to the University of California, at Berkeley, Calif., where he entered the Department of Civil Engineering.

In 1905, Mr. Shibley received the appointment of Assistant Engineer in the United States Reclamation Service, entering the Drafting Department, at Roosevelt, Ariz., during the construction of the Roosevelt Dam. He transferred to the Survey Division of the Reclamation Service, at Phoenix, Ariz., in 1907, in which position he had responsible charge of canal surveys for the Salt River Valley Project. In 1910, he was engaged in private practice of engineering, with an office in Mesa, Ariz. From 1911 to 1914, he served as Assistant Engineer in the U. S. Reclamation Service, with headquarters at Las Cruces, N. Mex., during the construction of the Elephant Butte Dam.

Mr. Shibley returned to Los Angeles, Calif., in 1914 to become affiliated with the Pacific Coast Office of the New York Continental Jewel Filtration Company, and had charge of the construction of the first large municipal filtration plant on the Pacific Coast, in San Diego, Calif. In 1915, with the organization of the California Filter Company, he moved to San Francisco, Calif., and became Manager of that Company. Mr. Shibley had the distinction of installing the first chlorinator for a domestic supply on the Pacific Coast.

In 1915 and 1916, he was the Agent of the Electro Bleaching Gas Company, of New York, N. Y., on the sale of chlorine and gas chlorinators for water supplies. In 1916 he became Agent of the Wallace and Tiernan Company, and continued in the field of water purification also as Manager and President of the California Filter Company. He continued in the latter position until 1933, when the Shibley Company, of Seattle, Wash., was organized.

---

[1] Memoir prepared by Paul F. Bovard, Mgr., California Filter Co., Inc., San Francisco, Calif.

In the Northwest Territory, Mr. Shibley made detailed studies of water supplies with special reference to pulp and paper manufacture. His articles, which appeared in the *Journal* of the Technical Association of the Pulp and Paper Industry, testify to his knowledge of the water requirements for this industry. His engineering ability in designing plants which were automatic in operation as well as economical testified to his ability in studying these particular problems. Practically all the large pulp and paper mills in the Northwest are equipped with water purification plants designed by Mr. Shibley. He was not satisfied with orthodox methods used in automatic control and, in recent years, had devised a remote control push-bottom system which operated large valves and pumps, giving records of operation, the accuracy of which has not been duplicated in any other system.

Mr. Shibley had an outstanding reputation both as an engineer of design and for salesmanship. His manner was characterized by extraordinarily quick mental reactions and his social contacts made lifelong friends among his clients. His large circle of friends over a long period of years, particularly among his clients, testified to the high esteem in which he was held by them and by members of the Engineering Profession. He will be long remembered as a distinctive character who enjoyed the reputation of an able engineer.

Mr. Shibley was not the type that enjoyed athletic exercise to any great degree, but he more than made up for this deficiency by his interest in athletics, and by his congenial personality and his enjoyment of short periods of recreation.

In 1906, he was married to Marian Bovard, of Los Angeles, Calif., who with a son, Bovard, and two daughters, Jean and Lillian, survives him.

In 1917, Mr. Shibley received a commission as Captain of Engineers in the United States Army, and served for the duration of the World War.

He was a member of the American Water Works Association and had the distinction of being a Charter Member and assisting in the organization of both the California Section and the Northwest Section of the Association; he was also a member of the Technical Association of the Pulp and Paper Industry. He was a Scottish Rite Mason and a member of Islam Shrine, of San Francisco.

Mr. Shibley was elected an Associate Member of the American Society of Civil Engineers on October 9, 1917, and a member on November 26, 1923.

AUGUSTUS SMITH, M. Am. Soc. C.E.[1]

Died February 29, 1932

Augustus Smith was born in New York, N. Y., on July 30, 1868, the eldest son of Henry Atterbury Smith and Rosena Watson (Ryder) Smith. His father was born in Hickley, Leicestershire, England, emigrated to New York in 1838, and at the time of his death in 1891 was a prosperous manufacturer of wall-paper. The Smith family occupied a great brownstone house in the far West Forties of New York City. The four sons—Augustus, Henry Atterbury, Arthur, and Oliver—were "earmarked" early in life as engineer, architect, lawyer, and business man, and each lived to achieve success in his chosen calling. Their home training was free from supernatural sanctions, and in their leisure they played string quartets and chess, and painted in oils. The architect—Henry Atterbury Smith, M. Am. Soc. C. E.—is the sole survivor of this interesting quartet.

---

[1] Memoir prepared by Alger C. Gildersleeve, M. Am. Soc. C. E.

Augustus Smith was educated in the Public Schools of New York City, received his Bachelor of Arts Degree from the College of the City of New York in 1887, entered the School of Mines, at Columbia University in New York City, in the Junior year, and was graduated in 1889 with the degree of Civil Engineer. He was a member of the Phi Beta Kappa Society.

Soon after his graduation from Columbia the Link Belt Company had an opening in its Philadelphia, Pa., Office for a Draftsman, and Mr. Smith applied for the job. As he entered the door, he encountered his classmate, Charles Piez, a rival applicant. The Link Belt Company showed its good judgment by hiring both boys. After not many years Mr. Piez was made President of the Company; and Mr. Smith became Head Draftsman in the New York Office, and then Engineering Salesman.

In 1893, he opened his own office in New York City as Engineer and Contractor, and, in 1906, incorporated the Bergen Point Iron Works of Bayonne, N. J. He was President of this Company until his death. As a Contracting Engineer his most important works were the two great coaling stations for the Panama Canal at Cristobal and Colon, the cost of which was about $2 000 000; and two others for the United States Navy—one at Narragansett Bay, R. I., and the other at the New York Navy Yard, in Brooklyn, N. Y.

Augustus Smith considered himself as a "plain man" and "of the people," his personal habits testifying to his natural asceticism; his beautiful residence, "Frogwood," in Roselle, N. J.; his unique summer home, "South Dunes," at Bay Head, N. J.; his motor cars and his yacht, were acquired against his natural inclination, and he always felt a bit uneasy over them.

In his youth, Augustus Smith was greatly impressed with the works of Jonathan Swift, and later in life he often quoted "Gulliver" in his talks and writings. Swift's bitter indictment of his fellow men roused an ambition in Mr. Smith to do what he could to remedy these evil manners of mankind, and to this end he applied himself diligently to the study of social concepts and problems. The origin and nature of the sense of duty, the validity of the concept of natural rights, and the meaning of justice, were themes that were always before him, and for which he was trying to develop workable formulas.

His philosophy, although he never claimed one, was essentially pragmatic. The mysteries of the stars and atoms, as elucidated by the modern physicists, meant as little to him as the promulgations of the mystics.

After profound study of the writings of Adam Smith, Karl Marx, François Fourier, and others, he made a laboratory of his Bergen Point Iron Works, testing a "Compensation Plan" by which the profits were equably divided between "Capital," "Talent," and "Labor." The plan operated successfully for many years, but failed to meet the problems of the "Great Depression."

In 1924, he was appointed to the New Jersey State Board of Commerce and Nagivation, and for many years inspected the waterways of his adopted State in his motor yacht, *The Gambolier*. This boat had been built from his own plans, and when he loaned it to the Government during the World War the engine was found to be of such unique construction that none of the personnel could fathom its intricacies, and it was returned to him with thanks.

He took an active interest in the civic affairs of his home town—Roselle—and was a member of the Borough Council there for three years, acting as Head of the Public Works Department.

Joining the American Economic Association, he was for a time an ardent disciple of Professor Irving Fisher, of Yale University, and supported the effort to make a science of economics with the "yardstick of value," the "money illusion," and other ideas. Although the two economists did not always agree, they had a great respect for each other's opinions—the Professor sometimes sending his manuscripts to the Engineer for comments, which were promptly returned on many closely typewritten pages. Professor Fisher's adherence to the "prohibition illusion" was a shock to Mr. Smith's conceptions of "natural rights."

Augustus Smith was a voluminous letter writer, and at times privately printed little pamphlets which he presented to his friends. In these essays he presented his views on various subjects of contemporaneous interest. His paper on the Narragansett Bay Coaling Station was published by the Society[2] in 1906. With the exception of discussions of various papers, he left no other published works. He sometimes tired of the pseudo-sciences, and his escapism—entertainment without any social purpose—was a correspondence on pure mathematics conducted with a few chosen friends. In one of his last letters he proposed a problem of which his death sealed his solution.

He was a Member of the American Society of Mechanical Engineers, the Franklin Institute, and the American Economic Association.

In 1903, he was married to Harriet Christine Davies, who died the following year; in 1907, he was married to Anna Barbara Such, who died in 1917. An only child—by his second wife—is Henry Such Smith.

Mr. Smith was elected a Member of the American Society of Civil Engineers on June 4, 1902.

BERNHARD ALEXANDER SMITH, M. Am. Soc. C. E.[1]

DIED MARCH 1, 1936

Bernhard Alexander Smith was born at Stawell, Victoria, Australia, on December 4, 1863, the son of Bernhard Smith, Police Magistrate, and Olivia

---

[2] "The Narragansett Bay Coal Depot," by Augustus Smith, *Transactions*, Am. Soc. C. E., Vol. LVII (December, 1906), p. 204.

[1] Memoir prepared by George Higgins, M. Am. Soc. C. E.

Frances Josephine (Boyes) Smith. His father was a noted amateur artist of the pre-Raphaelite school.

Bernhard Alexander Smith was educated at the Stawell Grammar School, at Queen's College, St. Kilda, Melbourne, Victoria, Australia, and at the University of Melbourne, obtaining the Argus Scholarship in Engineering at the Final Honor Examination at the University.

His first professional engagement was that of Engineer to the contractors for the construction of a railway line between Melbourne and Kew. In the following year, 1886, he obtained a Surveyor's License for the Colony of Victoria. Between 1888 and 1894, he practised in partnership with Mr. T. C. Hodgson. In 1890, Mr. Smith obtained the Certificate of Qualification as an Engineer of Water Supply under the Victorian Water Act of 1890; and for part of that year he taught at the Scotch College, which is one of the six Associated Public Schools of Victoria. The University of Melbourne also appointed him Lecturer in Surveying, Leveling, and Practical Mensuration. In 1891, when the same University appointed him Lecturer on Hydraulic Engineering, he resigned his lectureship in Surveying.

During the years 1899 to 1901, Mr. Smith practised in partnership with Mr. A. G. M. Michell, who later acquired world-wide fame as the inventor of the Michell thrust bearing, the crankless engine, the turbo-pump, the tangent jet wheel, etc., and whose scientific writings are widely read.

In 1903, he obtained a Surveyor's License for the State of New South Wales, and, in 1904, he obtained a Special License under the Real Property Act of 1900, in that State.

Mr. Smith reported on, designed, and constructed numerous works, the variety of which will be evident from the following examples: The design and supervision of installations of sewerage works at Horsham and Swan Hill, and preliminary reports for Warragul, Bairnsdale, Seymour, and Wodonga. He was consulted in Court cases about flood damage (Vinnicombe *v.* Macgregor; Colonial Ammunition Company *v.* Commissioners of Railways; and Kanuluik *v.* Mayor of Hawthorn). He also made reports and, where necessary, designs for storm-water drains for the Cities of Caulfield and St. Kilda; designs for the repair of the damage done by floods at Kooyong Tennis Courts; and for a flood bank around Moyne Swamp. He also reported on the obstruction caused to the River Yarra by the railway bridge at South Yarra, and on the flooding due to overflow of Moonee Ponds Creek.

He constructed the arched dam, 77 ft high, at Mount Cole, Ararat; the pumping plant, water tower, and treatment works, at Bairnsdale; the arched dam, turbines, motors, etc., for a private hydro-electric project; and the new reticulation mains for Seymour. He made reports on the remodeling of the water supply, of Shepparton; the pumping plant for Swan Hill; the water supply for Tallarock; the Yuthong hydro-electric project; a water tower, pumping plant, weir, reticulation, etc., at Wangaratta; the pumps and 1 000 000-gal reinforced concrete tank, at Warragul; a complete pumping water-supply project for Wodonga; the hydro-electric project for Stawell; the water supply for Camperdown and Terang; the water-works for Lismore; the installation of a water supply at Lorne, Maffra, and Mansfield; and on the water supply for Murtoa, Sunbury, Trafalgar, and Glenrowan. (All these places are in the State of Victoria.)

Mr. Smith also installed a water supply system, at Devonport, Tasmania; and reported on drainage in the vicinity of certain creeks, in the Riverina District, New South Wales.

The surveys and plans for a steam tramway for a mining company, in Tasmania, were made by Mr. Smith, as well as the valuation of the Brisbane (Queensland) Tramways prior to their transfer from a private company to the Government; he also prepared the valuation of the Melbourne (Victoria) Tramways in a similar case.

Installations for heating and ventilation were made by Mr. Smith for a tannery, at Preston; a soap factory, at Ballarat; a biscuit factory, at South Melbourne; a brewery at Abbotsford; a coffee palace, in Melbourne; the Melbourne Hospital, and three other hospitals in Melbourne, namely; the Children's, the Women's, and the Queen's Memorial for Infectious Diseases. The installations for electricity supplies for the Towns of Maffra, Cowes (Philip Island), and Horsham, as well as for the Shire of Upper Murray, were also a part of Mr. Smith's work, which included the construction of a bridge over the Tambo River, at Swan Reach, Victoria and a concrete stand at the Melbourne Cricket Ground.

Mr. Smith was the author of the following technical papers, etc: "Dynamical Models"[2]; "Michell's Method of Testing Fans"[3]; "Transition Curves"[3]; "The Comparison of a Tape with the Melbourne Observatory Standard"[4]; "A Test for Heat Insulators"[5]; "Town Sewerage"[6]; "Ventilation of Buildings"[7]; "Arched Dams"[8] (for which he was awarded the J. James R. Croes Medal in 1920, by the American Society of Civil Engineers); and "Experimental Deformation of a Cylindrical Arched Dam"[9].

He became a member of the Victorian Institute of Surveyors in 1889. In 1914, Mr. Smith was elected a member of the Victorian Institute of Electrical Engineers, and of the Melbourne University Engineering Society. In 1918, on the inception of the Public Health Commission of Melbourne, he was elected a member of the Commission. The year, 1923, marked his election as Fellow of the Victorian Institute of Surveyors, a member of the Faculty of Engineering of the University of Melbourne, and a member of the Victorian Lifts Board. In 1925, Mr. Smith became Chairman of the Melbourne Division of the Institution of Engineers, Australia, and, in 1928, he served as President of that Institution. He was a member of both the Australasian and the British Associations for the Advancement of Science.

[9] *Loc. cit.*, Vol. 91 (1927), p. 705.

Mr. Smith's principal recreation was music, the piano being his favorite instrument. It was at his suggestion that arrangements were made for an excellent series of orchestral concerts in Melbourne, which were conducted by the late Professor Marshall Hall.

His friends will remember him for his cordiality and kindliness, his courtesy and consideration for the opinions of others. In the Engineering World he set an example by his patient conscientious search for accuracy.

His marriage to Agnes Janet Shields, the daughter of a prominent Melbourne physician, took place on December 13, 1899. He died at Armadale, Victoria, on March 1, 1936, retaining his intellectual keenness during a long period of bodily weakness, and is survived by his widow, one son, and two daughters. The son, Mr. D. Bernhard Smith, had been his partner for a number of years. A distinguished cousin of Mr. Smith who predeceased him by a few years, was Philip a' Morley Parker, M. Am. Soc. C. E., the author of the well-known treatise on "The Control of Water".

Mr. Smith was elected a Member of the American Society of Civil Engineers on June 18, 1918.

EUGENE RAYMOND SMITH, M. Am. Soc. C. E.[1]

Died January 14, 1938

Eugene Raymond Smith was born in Brooklyn, N. Y., on February 10, 1858, the son of Charles Carpenter and Adelia (Hawkins) Smith. His parents later removed to Islip, N. Y., where he received his early education in the public schools. Later, he entered Cornell University, at Ithaca, N. Y., from which he was graduated in 1877 with the degree of Bachelor in Civil Engineering.

From 1877 to 1880 Mr. Smith was employed as Assistant Engineer on the construction of the Burlington, Cedar Rapids and Northern Railroad; Assistant Inspector of dredging at Cherry Island Flats and Bulkhead Bar, on the Delaware River; and Assistant Engineer in charge of construction on the Denver and Rio Grande Railroad in Price River Canyon, Utah.

In 1880, he decided to go into private practice and opened an office in Islip as a Civil Engineer and Surveyor. His practice was of a highly varied character, calling for knowledge of engineering fundamentals and ingenuity. Among the prominent projects with which he was connected, were the following: The location and alignment of the Long Island Motor Parkway; Long Island State Park Commission in its early days; the formation of the Fire Island State Park as a park; the first grade-crossing elimination work in Western Suffolk County, New York, at the Cutting and Vanderbilt crossings of Merrick Road and the Long Island Railroad; and the development of the incorporated Village of Brightwaters and "Idlehour," formerly the estate of the late W. K. Vanderbilt, in Oakdale, N. Y. He was in charge of the construction of the trout preserve at Wantagh, N. Y., and also at Nissequogue, N. Y., for the Nissequogue Trout Club; of the field work at the New York City Insane Asylum, at Central Islip, on sewer work, etc.; location survey maps and profiles for Kings, Queens, and Suffolk Railroad Company from the Brooklyn City line to Far Rockaway, N. Y.; of the reclamation of 80 acres of salt marsh land at Islip, and of the reclamation of salt marsh land at Broad Channel, Jamaica Bay, New York; the extension of the distribution system of Northport Water Works Company, Northport, N. Y.; and several small dredging improvements on the south side of Long Island, New York. Mr. Smith's reputation as a Surveyor was such that in preparing the Hyde Atlas of the southern shore of Long Island, his collaboration was eagerly sought.

---

[1] Memoir prepared by Robert J. Bartley, M. Am. Soc. C. E.

His varied experience with land reclamation on the south side of Long Island, led to his paper on the "The Compressibility of Salt Marsh Under the Weight of Earth Fill."[2]

Mr. Smith was always the student, well informed, independent, and liberal in his views. He was the kind of engineer who did not believe that his value to society ended with purely engineering work. Being of a kindly nature, his keen sense of humor was always a source of pleasure to his friends.

His community activities included: Treasurer of the Islip Methodist Episcopal Church and President of its Board of Trustees; Chief of the Islip Fire Department; President of the Library Board; President of the Islip Board of Education; President and Director of the First National Bank of Islip; and Director of the First National Bank of Bay Shore, N. Y. Mr. Smith was a Past-President of the Nassau-Suffolk Civil Engineers, Incorporated, and a member of the New York State Association for Professional Engineers and Land Surveyors.

He was married, in 1885, to Maywood Clock, of Islip, who, with a son, Rodney J. Smith; a daughter, Marian (Smith) Williams; a grand-daughter, one sister, and two brothers, survives him. He retired from active business in 1926, but retained his interest in banking until about 1933.

Mr. Smith was elected a Junior of the American Society of Civil Engineers on May 2, 1888, and a Member on May 1, 1901.

CHRISTOPHER HENRY SNYDER, M. Am. Soc. C. E.[1]

DIED MAY 27, 1937

Christopher Henry Snyder, the son of William Cowperthwait Snyder and Isyphene Caroline (Pearce) Snyder, was born in Fulton, Ill., on June 12, 1866. His father was engaged in shipping and warehousing in Fulton at a time when the Mississippi River was an important trade route and Fulton a distributing point for Northwestern Illinois.

---

[2] *Transactions*, Am. Soc. C. E., Vol. XXXVII (June, 1897), p. 213.

[1] Memoir prepared by Frederick R. Muhs, M. Am. Soc. C. E.

As a boy, Mr. Snyder attended the public schools at Fulton, later entering the University of Illinois, at Urbana, Ill., from which he was graduated in 1890 with the degree of Bachelor of Science in Civil Engineering. After graduation Mr. Snyder spent three years as a Draftsman with the Keystone Bridge Company, two years of which were spent in the Chicago Office, and one year at the plant in Pittsburgh, Pa.

In 1893 he became associated with Milliken Brothers, Incorporated, of New York, N. Y., working for five years as a Draftsman, two years as Chief Draftsman, two years as Contracting Engineer at Honolulu, Hawaii, and ten years as Contracting Engineer, at San Francisco, Calif.

In 1912 he opened an office in San Francisco as a Consulting and Designing Engineer for structural work, and continued his practice until his death, on May 27, 1937. Some of the buildings for which he designed the structural frames are as follows: Department of Labor and Interstate Commerce Building, Washington, D. C.; City Hall, Federal Building, War Memorial Opera House, and Veterans Building, City and County Hospital, Relief Home, University of California Hospital, 450 Sutter Building, and the Pacific Gas and Electric Company Office Building, in San Francisco; Stanford University Library, Palo Alto, Calif.; Pasadena City Hall, Pasadena, Calif.; Makee Sugar Company Mill, and the American Sugar Company Mill, in Honolulu.

When concrete became an important material in structures, Mr. Snyder designed and patented a "flat slab-steel frame" construction for buildings, which was used in many of the modern buildings.

On October 14, 1899, Mr. Snyder was married to Harriet Runyon, to which union the following children were born: Henry R., William C., Helen J., and John R. Mrs. Snyder and the children survive him.

Mr. Snyder was interested in the raising of engineering standards and served on many committees having to do with the welfare of the Civil Engineering Profession. His professional affiliations included the San Francisco Section of the Society (President, 1914), the Western Society of Engineers, and Pacific Association of Consulting Engineers. He was a Charter Member and assisted in organizing the Structural Engineers Association of Northern California (President, 1934). He was also a member of the Engineers' Club of San Francisco (President, 1925–26); the Union League Club, Commercial Club, Commonwealth Club, Kiwanis Club, and the Olympic Club, all of San Francisco; the Claremont Country Club, of Oakland, Calif.; and the Mount Diablo Country Club, of Danville, Calif. His principal recreations were music and golf.

A fitting tribute[2] to Mr. Snyder was paid by Arthur Brown, Jr., a San Francisco architect, which is here quoted in full:

> "The architectural and engineering fraternity has lost one of its most distinguished and outstanding members by the death of Christopher H. Snyder. For the past thirty years he was intimately associated with the design and execution of much of the important engineering and architectural construction that has been done in the San Francisco Bay region, and the

---

[2] *The Architect and Engineer,* June, 1937.

architects for whom he acted in the capacity of consulting and designing engineer will always be grateful to him for his splendid work in structural design, upon which they could confidently depend.

"C. H. Snyder was singularly fitted for his task as designing and consulting engineer for the architectural structures to which he gave so much of his professional attention. Thoroughly schooled in engineering theory at the University of Illinois, he passed a long apprenticeship in practical application in the steel manufacturing plant of the Keystone Bridge Company. Following his training in structural design from the producer's standpoint, he joined the organization of Milliken Brothers, contractors, where he had many years of experience and responsibility in the actual administration and execution of engineering enterprises of the first order.

"These three phases of his career rounded out and completed his highly competent professional equipment. His recommendations could be confidently depended upon for rational design and feasibility, and his estimates of cost were based on positive knowledge and experience. Thus he was an invaluable collaborator for those architects with whom he was associated. His designs were always simple and direct—as was his personal character. His brilliant engineering imagination was founded on precise knowledge and his ingenuity and resourcefulness followed naturally from a thorough familiarity with the details of his craft. He did not consciously concern himself with making engineering history, but concentrated his attention strictly to his prime objective of conceiving safe, practical and economical structures. His drawings were models of clearness and gave precise, systematic and complete information. Possessed of high ideals he never wavered in defending his convictions; nor was he known to compromise on safety and good practice.

"Mr. Snyder's professional qualities were a clear reflection of his temperament. He had little sympathy with the vague experiments of some of the innovators in either engineering, economics, or politics, but defended sturdily the fundamental convictions born of his long experience of life and professional endeavor. He believed in hard steel, hard dollars, and hard common sense—in spite of new trends. These high qualities were generally recognized and, consequently, he enjoyed the highest respect of every one in the community.

"His friends will long mourn his passing and will long cherish the memory of a stalwart and likable personality."

Mr. Snyder was elected a Member of the American Society of Civil Engineers on October 2, 1901.

EDWARD EVERETT STETSON, M. Am. Soc. C. E.[1]

DIED JULY 13, 1937

Edward Everett Stetson was born at Mattapoisett, Mass., on October 8, 1882. His parents were Everett Cortez and Annie (Hiller) Stetson. Both families were pioneers in New England, coming from England to Massachusetts in the early part of the Seventeenth Century (the Stetsons in 1634 and the Hillers in 1629). The stock was strong and hearty on both sides, and produced many people of note during the three centuries. Mr. Stetson's grandfather was the Captain of a whaler, and his father, still hale and hearty at the age of 84, is a land-owner and lumber-mill operator in Mattapoisett.

---

[1] Memoir prepared by Joshua D'Esposito and Einar Weidemann, Members, Am. Soc. C. E.

Mr. Stetson had his early schooling at Mattapoisett and, later, went to High School, at Fair Haven, Mass. Between times he worked on his father's farm and in the mill. In High School he gave such a good account of himself as a student in mathematics that the Principal persuaded his father to permit him to study Engineering instead of returning to the farm and lumber mill as originally planned. He entered the Massachusetts Institute of Technology at Boston, Mass., and received his degree of Bachelor of Science in Civil Engineering in 1904. Immediately after his graduation, Mr. Stetson spent some time at survey work in Sheffield, Pa., but in September of the same year he was called to his Alma Mater as an Instructor of Railroad Engineering and remained in this position for a year.

His desire for practical railway work was realized in 1905, when he accepted a position as Levelman with the Pennsylvania Railroad Company, with headquarters at Pittsburgh, Pa. Mr. Stetson quickly impressed himself as a young man of outstanding character and ability, and as early as 1909 he had been advanced to the position of Engineer in Charge in the Office of the Chief Engineer, Maintenance of Way.

During these earlier years of his career, his clear analytical mind contributed some valuable research work, particularly on stresses in railroad tracks, at that time a subject about which information was greatly lacking.

During the period from 1909 to 1916, Mr. Stetson was actively engaged as Engineer in Charge of Construction of several track-elevation projects undertaken by the Pennsylvania Railroad Company, principally in Columbus and Cincinnati, Ohio. This difficult class of work which requires the maintenance of railroad operations simultaneously with the procedure of the construction work, and which is often made more complicated by the frequently diverging interests of the municipalities, contractors, and railroad company, gained for him valuable experience that stood him in good stead in his later career.

At the outbreak of the World War and particularly during the United States Railroad Administration, many new facilities were called for, and Mr. Stetson returned to Pittsburgh in 1916, to service as Assistant Engineer on the Staff of the Chief Engineer of Construction, directing various construction projects from Headquarters.

The Chicago Union Station Company was organized in 1915 and the construction of the new $100 000 000 passenger terminal was commenced in the fall of that year. This vast project, one of the greatest engineering undertakings of its time, called for the construction of new modern facilities on ground occupied by the old passenger and freight stations, without interruption to regular railroad traffic, a traffic which involved the handling of 250 to 300 passenger trains daily and a large amount of mail and express business. This work had scarcely been started when it had to be suspended temporarily on account of the war, and it was not before the early part of 1919 that construction work was resumed in a vigorous manner. That the choice then fell upon Mr. Stetson to fill the difficult position of Engineer of

Construction for this undertaking shows the high esteem in which he was held. Neither did he disappoint his superiors. His experience and ability as a construction engineer; his high degree of leadership; his fairness and sound judgment in all his dealings with the many contractors, railroad operating men, and the public in general, contributed in a large measure to the successful completion of the great project, the execution of which required a laboriously developed program for co-ordinated construction in piecemeal of miles of railroad tracks, viaducts, bridges, and buildings costing millions of dollars, temporary and permanent structures, all to be handled with the business of the railroad terminal going on as usual. It would be expected that such a great amount of work continuing for several years could not be completed without some serious accident. This was not the case, and it might be noted as a singular record that at the completion of the work there had been no single case of serious injury to passengers or public.

In 1923, Mr. Stetson was promoted to be Principal Assistant Engineer of the Station Project, but continued in direct charge of all construction work until its completion in 1926.

The late fall of 1926 found him returning to the Pennsylvania Railroad Company as Assistant to the Chief Engineer, with headquarters in Chicago, Ill. He remained in this position until his death and, during later years, was actively engaged in the direction and administration of various construction projects and grade separation work on the Western Region of the Railroad.

He was a member of the Western Society of Engineers and the American Railway Engineering Association.

His untimely and sudden death, after an operation, was a blow to his many friends who knew him as a strong and vigorous man who had never been on sick leave. Mr. Stetson was a man of quiet and unassuming manner, but one of energy and determination, and work entrusted to him would be sure of vigorous prosecution. He had little patience with delay and procrastination.

His many friends among the contractors will remember him as the practical and resourceful engineer, keenly interested in their work and always glad and ready to have them draw upon his engineering knowledge and experience. They will remember him as an eminently fair-minded arbiter, loyal to them, his company, and his conscience. The fact that his decisions were rendered with a characteristic smile only added to their effectiveness.

His more intimate friends will remember him as the strong and manly man he was—always poised, never excited. To the many younger engineers in charge of construction work under his direction, he was the safe haven they could rely upon when the sea became too turbulent. He was always their faithful friend and would always find a way.

He was married in 1908, to Hilda C. Amundsson, at Warren, Pa. His widow and two children survive him, Mrs. Helen (Stetson) Moore, of Dallas, Tex., and Everett Charles Stetson.

Mr. Stetson was elected a Member of the American Society of Civil Engineers on May 28, 1923.

HORACE STRINGFELLOW, M. Am. Soc. C. E.[1]

DIED JANUARY 1, 1937

Horace Stringfellow was born at Montgomery, Ala., on March 28, 1882. He was the son of the Rev. James Horace Stringfellow and Lula B. (Haskins) Stringfellow. For many years his father was Rector of Christ Church, at Tuscaloosa, Ala.

Mr. Stringfellow's boyhood was spent in Tuscaloosa, where he attended Verner's School. His family intended him for the ministry, and with that career in prospect he entered the University of Alabama, at University, Ala., in 1898. However, a previous six months as Rodman with the United States Corps of Engineers may have had a great deal to do with Mr. Stringfellow's change in profession to engineering. In any case he changed from the University of Alabama to the University of the South, at Sewanee, Tenn., from which he was graduated with the degree of Bachelor of Arts, in 1902.

During a summer vacation, and prior to his graduation, Mr. Stringfellow served as Topographer with the Mobile and Western Alabama Railroad Company. From January to May, 1903, he was employed as Transitman by the Mobile, Jackson and Kansas City Railroad Company; and from May, 1903, to April, 1905, he was engaged in the same capacity with the Southern Railway Company.

His service with the Southern Railway Company continued, with short interruptions in 1913 and 1918, for nearly twenty years. He was Assistant Engineer on construction from April, 1905, to September, 1913. From September, 1913, until January, 1914, he superintended the construction of concrete reservoirs at Lake Montebello for the City of Baltimore, Md.

From February to September, 1914, he was Field Engineer on valuation for the Atlanta, Birmingham and Atlantic Railroad Company, and from September, 1914, to December, 1917, he was Assistant Engineer on the Southern Railway engaged on surveys, reports, and construction, including the rebuilding of the Warrior River Bridge. From December, 1917, to August, 1918, he was District Engineer on the same railroad, in charge of double-track construction, which involved 42 miles of heavy work and the elimination of seven tunnels.

In August, 1918, Mr. Stringfellow was commissioned Captain of the 105th Engineers, serving at Camp Shelby, Mississippi. He remained there until his discharge from the Army on December 16, 1918.

He returned to the Southern Railway Company from January, 1919, to March, 1920, as District Engineer, and was in charge of double-track construction from Washington, D. C., to Central South Carolina. This work consisted of the construction of about 200 miles of additional main track, with important yard and terminal work.

---

[1] Memoir prepared by a Committee of the St. Louis Section, consisting of W. J. Burton and E. M. Durham, Jr., Members, Am. Soc. C. E.

In March, 1920, Mr. Stringfellow became Regional Engineer of the United States Railroad Administration, engaged in the liquidation of claims growing out of Federal control of railroads. This work was completed in 1924.

From 1924, until his death on January 1, 1937, Mr. Stringfellow was employed by the Missouri Pacific Railroad Company—first, as Engineering Assistant in the Executive Department and, later, as Executive General Agent at Denver, Colo. His work included a wide variety of special investigations and reports, involving traffic and operating problems, as well as those of an engineering nature. As Executive Assistant, he represented the President of the Company in many important matters.

Mr. Stringfellow combined engineering ability with good common sense. His pleasing personality and his ability to make friends were great assets in his work.

He was a member of the American Railway Engineering Association, and of the Bellerive Country Club, in St. Louis, Mo. He was a member of the Protestant Episcopal Church, and was an independent in politics.

In 1913, he was married to Virginia Mauney, who died shortly thereafter. In 1928, he was married to Ethel Jones Edmonds, who survives him.

Mr. Stringfellow was elected an Associate Member of the American Society of Civil Engineers on September 12, 1916, and a Member on April 26, 1921.

HARRY RANDOLPH TALCOTT, M. Am. Soc. C. E.[1]

Died April 6, 1937

Harry Randolph Talcott was born in Richmond, Va., on November 9, 1861, the son of Charles Gratiot and Theodosia (Lawrence) Talcott. For the preceding two generations the family had been actively associated in engineering work in the United States. His grandfather, Colonel Andrew Talcott, who was graduated from the United States Military Academy, at West Point, N. Y., in July, 1818, was in charge of the construction of fortifications at Fortress Monroe, Virginia, during which time General Robert E. Lee, as a Junior Lieutenant, was a member of his staff. His father, Charles Gratiot Talcott, for whom General Lee developed a strong affection through his frequent visits to his home, during the War between the States, served as a Captain on the staff of General Lee, in charge of railroads throughout the Confederate States. Mr. Talcott, in childhood, had the privilege of intimate association with General Lee, after the conclusion of hostilities, and thus, with his passing, one of the few remaining links with that period is dissolved.

Mr. Talcott was educated at the Episcopal High School, in Alexandria, Va., and Rittenhouse Academy, in Washington, D. C., from which latter institution he was graduated in June, 1878. His active career began in 1879, when he entered the service of the Chesapeake and Ohio Railway Company in the capacity of Rodman on preliminary surveys. He remained a member of the Chesapeake and Ohio organization, rising to the position of Resident Engineer on Construction, until May, 1882, when he resigned to enter the service of the Western North Carolina Railroad Company (later a part of the Atlantic Coast Line Railroad Company) as Assistant Engineer on Location, serving in that capacity until November of that year, when he resigned to accept a position with the United States Fish Commission as Assistant Engineer on Topographic Surveys, and in February, 1883, was engaged with the United States Coast and Geodetic Survey on the St. Johns River reconnaissance. In May, 1883, he returned to the Western North Carolina Railroad Company as Assistant Engineer on Location, remaining in this position until December of that year. In January, 1884, he entered the organization of the Richmond, Fredericksburg and Potomac Railroad Company as Assistant Engineer, but remained with the Company for a very short period.

---

[1] Memoir prepared by a Committee of the Maryland Section, consisting of Jenks B. Jenkins and H. A. Lane, Members, Am. Soc. C. E.

In February, 1884, Mr. Talcott entered the service of the Baltimore and Ohio Railroad Company as Assistant Engineer in charge of the Field Corps on the construction of the Susquehanna River Bridge, comprising a part of that railroad's extension to Philadelphia, Pa., which was then in process of construction. In January, 1885, he became Assistant Engineer in charge of the construction of the section of that line between Chester, Pa., and the Susquehanna River. In April, 1886, he resigned from the Baltimore and Ohio Railroad Company to enter the service of the Charleston, Cincinnati and Columbus Railroad Company as Transitman on Location. From July, 1886, to January, 1887, he was employed by Rice and Coleman, Contractors, as Superintendent on the construction of the Newbury and Augusta Railroad. Between February, 1887, and September of that year, Mr. Talcott was engaged by the East Lake Land Company as Assistant Engineer at Birmingham, Ala. From September, 1887, to May, 1888, he was engaged in a contracting business as a member of the firm of Haskell and Talcott, at Birmingham, Ala.; however, on the latter date, Mr. Talcott returned to railroad work, accepting a position as Transitman on Location with the Knoxville Southern Railroad Company, and in October, 1888, he became Resident Engineer on the construction of the Knoxville, Cumberland Gap and Louisville Railroad.

Between September, 1889, and July, 1892, he was employed by the Seattle, Lake Shore and Eastern Railroad Company (later a part of the Northern Pacific System), first as Assistant Engineer and then as Chief Engineer. From July, 1892, to March, 1894, he served as Second Vice-President of the Seattle Coal and Iron Company, in charge of that Company's mines and business in the State of Washington. Between the latter date and December, 1897, he acted as Agent for the Receiver of that Company and, at the same time, served as Chief Engineer of the Seattle, Lake Shore and Eastern Railroad Company. In June, 1898, he became Assistant to the Superintendent of Construction of the White Pass and Yukon Railroad, in Alaska; in December, 1899, he became Chief Engineer of the Seattle and International Railway Company and, in September, 1900, Resident Engineer in charge of the Seattle Division of the Northern Pacific Railway Company. Between December, 1901, and March, 1903, he was associated with his brother-in-law, the late Herman Hollerith. In this connection, he held the position of Treasurer of the old Taft and Pearce Machine Company, of Woonsocket, R. I.

In March, 1903, Mr. Talcott returned to the Baltimore and Ohio Railroad Company, with which Company he spent the remainder of his career. He was first employed as Assistant Engineer in charge of the office of the late Francis Lee Stuart, Past-President, Am. Soc. C. E., District Engineer, at Cumberland, Md., and, later, in charge of miscellaneous surveys in that office. In March, 1905, he was transferred to the main office at Baltimore, Md., as Engineer of Surveys.

In order to carry out the provisions of Section 19*a* of the Interstate Commerce Act, known as the "Valuation Act," approved March 1, 1913, a Valuation Committee was appointed for the Baltimore and Ohio System, with Mr. Talcott as its Chairman, about January 1, 1914, and in June, 1917, he was appointed Assistant Chief Engineer, which positions he occupied at the time of his death.

Although he was engaged at various times in railroad construction and operation, his principal activities since his return to the Baltimore and Ohio System in 1903 were in the fields of locations and surveys, and under his jurisdiction surveys for a number of important projects were made, embracing: Improvement of the grade and alignment over the Allegheny Mountains, which included the present double-track Sand Patch Tunnel, on the Chicago Line, having a length of 4 475 ft, at the summit of the Allegheny Mountains; improvement of the St. Louis Line on the west end of the Cumberland Division, which included the change of line and reduction of grade west of Cheat River, between Blaser and West End, W. Va., on which is located the present double-track Kingwood Tunnel having a length of 4 202 ft; and improvement of the east end of the Cumberland Division, which included the Magnolia Cut-Off east of Cumberland, Md., in the Potomac River Valley, where the river is deeply entrenched on a meandering course through the eastern front of the Allegheny Mountains; this cut-off is 13.2 miles long, has four tunnels aggregating 6 958 ft in length, two crossings of the Potomac River, and effects a saving of 5.7 miles in main-line distance.

Mr. Talcott was a member of the American Railway Engineering Association; a member of the Engineers Club of Baltimore; a life member of the National Geographic Society; and a member of the New York Historical Society. He was a member of the Protestant Episcopal Church.

He was never married. His entire life was dedicated to his work, which he performed with exceptional ability and energy. He was a great lover of the out-of-doors; philosophical by nature, and of the highest integrity and the finest character, a true and helpful friend who had the love, respect, and admiration of all his associates. He always showed great sympathy for those in trouble, and the help he gave to them was proverbial. Through the advice of Mr. Talcott, many a young man was aided and guided in his course in life. His passing is a great and distinct loss to his many friends and to the profession.

Mr. Talcott was elected a Member of the American Society of Civil Engineers on October 5, 1904.

ROBERT BRUCE TINSLEY, M. Am. Soc. C. E.[1]

Died February 24, 1937

Robert Bruce Tinsley was born in Danville, Va., on August 24, 1883. His parents were James Whitfield and Nannie (James) Tinsley. He was graduated from the Radford, Va., High School. From this institution, for outstanding work in his studies, he received a scholarship to St. Albans Preparatory School, at Radford, in 1900. On leaving St. Albans, he entered the Virginia Polytechnic Institute, at Blacksburg, Va., where he continued until 1905, pursuing a course in Civil and Mining Engineering. During his vacations, he gained practical experience in his chosen profession by working for a firm of consulting engineers engaged in railroad location, underground mine surveys, coke-oven construction, etc.

On the completion of his studies at the Virginia Polytechnic Institute, Mr. Tinsley accepted a position as Transitman and Assistant Resident Engineer with the Southern Railway Company, at Bristol, Va.-Tenn., where for a year, until January 1907, he was engaged on railroad location and construction in the adjacent mountain country. Next followed six months of work, for a firm of consulting engineers, devoted largely to field problems in connection with railroad location and mining developments. During the next year, he was engaged in underground mine surveys, and, as Resident Engineer for the Chicago, Indianapolis, and Evansville Railroad Company, he located a 65-mile line from Vincennes to Evansville, Ind. From July, 1908, to July, 1909, Mr. Tinsley was Chief Engineer of the New Mexico Midland Railroad Company at San Antonio, N. Mex., and its subsidiary, the Carthage Fuel Company, of Carthage, N. Mex. In this capacity he relocated and constructed sections of 16 miles of mountain railroad, and directed the underground surveys for three large coal mines, together with the essential diamond-core drill work.

From July, 1909, to May, 1914, Mr. Tinsley was engaged in several capacities in connection with the construction of the Panama Canal and was employed, successively, as Transitman, Junior Engineer, Assistant Engineer, and, finally, as Superintendent of Construction in the Pacific Division. During this time he was first in charge of the layout work for the Pedro Miguel Locks and Dams; then Superintendent of Construction on the Miraflores Lock, hydraulic core-dam, spillway dam, and electrical control houses for the Pedro Miguel and Miraflores Locks, the Cristobal Coaling Station, and later, directed the work of the hydraulic sluicing plant at Gold Hill, Culebra Cut. For his excellent work in connection with the performance of the aforementioned duties, he received letters of commendation from the late General George W. Goethals, U. S. Army, M. Am. Soc. C. E., and S. B. Williamson, M. Am. Soc. C. E., the Division Engineer.

In May, 1914, Mr. Tinsley accepted a position as Manager and Engineer for the General Asphalt Company, at Guanoco, Venezuela, and performed work involving railroad and channel maintenance, dock and road construction, camp sanitation, and water supply.

---

[1] Memoir prepared by H. B. Smith, Engr., and I. H. Patty, Associate Engr., U. S. Engr. Office, Galveston, Tex.

He became Division Superintendent of Construction and Resident Engineer for the Chile Exploration Company, at Chiquicamata, Chile, in January 1916, and continued in this capacity for nearly two years. As such, he had direct charge of the construction of a $39 000 000 copper leaching plant, which involved the construction of railroads, highways, two 67-mile desert pipe lines, dams and storage reservoirs for water supply, and the installation of electric-generating machinery and equipment, and other construction activities. When he left the services of this Company, his associates and employees presented him with a fine gold watch.

With the outbreak of the World War, Mr. Tinsley volunteered his services in defense of his country. He entered the service in January, 1918, and served with distinction as Captain of Company C, 605th Engineers, with the American Expeditionary Force in France. At the completion of his military service in July, 1919, the men of his Company, as a token of their high esteem for him, presented him with a loving cup.

Soon after returning to private life, Mr. Tinsley became President and General Manager of the Crest Coal Company, of Big Stone Gap, Va., and continued in this capacity until April, 1924. During the summer of this year, he was again in Government service as Superintendent of Construction of Lock and Dam No. 50, Ohio River, reporting to the District Engineer, Louisville, Ky., District.

Retiring again from Government service he was for two years Vice-President and General Superintendent of the Smith Company, of Birmingham, Ala. With this firm he was in direct charge of the construction of steel and concrete bridges and important municipal utilities. In September, 1926, Mr. Tinsley became Resident Engineer for the City of Lexington, Va., and while holding this position he had charge of the engineering and construction of a large earth dam for the city water supply. In 1928, he became Consulting Engineer for the Town of Big Stone Gap, where he directed a water-shed survey and an investigation on water supply possibilities. At the conclusion of this work, in the same year, he constructed three highway bridges for the Jordan Construction Company, of Albany, N. Y.

In October, 1928, Mr. Tinsley accepted a position with the United States Engineer Department, New Orleans, La., where he was in charge of general channel rectification work and maintenance of navigation in South Pass and Southwest Pass at the mouth of the Mississippi River. This work included bank revetments, construction of jetties, bulkheads, spur-dikes, and hydrographic and hydrometric surveys. While engaged on this work he was also associated with the performance of three important hydraulic model studies for channel improvement at the Passes of the Mississippi River, which were made at the United States Waterways Experiment Station, at Vicksburg, Miss. As a result of these model studies, new works were designed and constructed which resulted in marked improvement of the channel.

Early in 1935, he accepted a transfer to the United States Engineer Office, at Galveston, Tex. In this office he held the position of Senior Engineer, in charge of the General Engineering Division. His work in this connection, until the time of his death, comprised among other things, the making of engineering studies and the preparation of reports in connection with river and harbor improvements for flood control and navigation.

Mr. Tinsley was married on October 23, 1907, to Sue Goodloe, daughter of John and Elizabeth (Ferguson) Goodloe. He is survived by his widow and an only son, John Goodloe Tinsley. He was a member of the American Institute of Mining and Metallurgical Engineers, and the Society of American Military Engineers.

He was a man of rare personal charm and magnetism, and always made for himself a large number of friends and admirers among those with whom he was associated. Apropos of this, it is fitting to quote the following from the pen of Lieutenant Colonel E. H. Marks, U. S. District Engineer, M. Am. Soc. C. E., at Galveston, under whom Mr. Tinsley last served:

> "Robert Bruce Tinsley had a great wealth of varied experience but perhaps of even greater value was his devotion to his duties and his kindly considerate treatment of others. To him no task was done unless it was well done. Always working regardless of hours he gave the most meticulous attention to details of estimates and designs and was unsparing of himself in carrying out his tasks. Those privileged to work with him were always mindful of his friendly advice and encouragement. He was a fine Virginia gentleman."

Mr. Tinsley was elected an Associate Member of the American Society of Civil Engineers on February 6, 1912, and a Member on October 9, 1917.

ARTHUR CARLING TONER, M. Am. Soc. C. E.[1]

DIED SEPTEMBER 4, 1937

Arthur Carling Toner was born in Baltimore, Md., on November 21, 1881, the son of John M. and Kate (Carling) Toner. His early education was obtained in the public schools of Baltimore. In 1898, he entered the University of Virginia, in Charlottesville, Va., where he studied for a little more than two years. Mr. Toner then studied for three years at the University of Pennsylvania, in Philadelphia, Pa., and was graduated in June, 1904, with the degree of Bachelor of Science in Civil Engineering.

Mr. Toner was closely connected with the construction industry throughout his life. His earliest employment after graduation was with the Latta and Terry Construction Company for which firm he had worked during college vacation periods as Instrumentman and Timekeeper. Between 1904 and 1906, he was Engineer and Assistant Superintendent on electric railway construction and improvements at the United States Naval Academy, in Annapolis, Md., for which the Latta and Terry Construction Company were the Contractors. Following the completion of the work at the Naval Academy, Mr. Toner entered the employ of the Baltimore Sewerage Commission, with which he remained until January, 1914. During this period, while Mr. Toner was Resident Engineer in charge of construction, extensive improvements were made in the system, including the construction of several large interceptors and the tunnel for Jones Falls Conduits.

---

[1] Memoir prepared by Claude A. Webb and Leo H. Corning, Assoc. Members, Am. Soc. C. E.

The construction experience thus gained by Mr. Toner equipped him for his next position, taken in January, 1914, with the Association of American Portland Cement Manufacturers, later, the Portland Cement Association. With headquarters in Philadelphia, Mr. Toner was Field Representative in the southeastern part of the United States, doing educational and engineering work pertaining to various uses of cement and particularly concrete highway construction. Much of his work consisted of acting in a consulting capacity on the preparation of plans and specifications and on the construction of projects involving the use of concrete.

In August, 1916, Mr. Toner became District Engineer for the Portland Cement Association, with headquarters in Pittsburgh, Pa. In that position, he was in charge of the work of the Association in Ohio and Western Pennsylvania. With the outbreak of the World War in April, 1918, he was given a leave of absence by the Portland Cement Association and became Assistant General Manager of the Liberty Shipbuilding Company, in Boston, Mass., Contractors for the Emergency Fleet Corporation. He was at Wilmington, N. C., for about four months as General Assistant in the organization of a construction force and the building of a shipyard for the construction of concrete ships. Later, he was in charge of the Brunswick, Ga., Yard for about six months as Representative of the Contractors for the Emergency Fleet Corporation. While at the Brunswick Yard the concrete ship, *Atlantus,* was built under Mr. Toner's supervision.

In February, 1919, Mr. Toner again rejoined the staff of the Portland Cement Association as District Engineer in Pittsburgh. In 1925, he became Regional Manager of the Mid-Eastern Region of the Portland Cement Association, with headquarters in the same city. In June, 1929, he was transferred to the Washington, D. C., Office as Manager, where he remained until 1933. Ill-health forced his temporary retirement at that time, but, later, he was able to resume active work with the Association in its General Office, in Chicago, Ill., where he remained until his death. During President Hoover's administration, Mr. Toner served on the President's Committee for the Unemployed.

During the period of his connection with the cement industry from 1914 until 1937, Mr. Toner contributed much to its progress. He saw the general adoption of concrete highways, the extensive use of concrete in bridges and buildings, and an increase in the consumption of cement from 88 000 000 bbl per yr to a maximum of 176 000 000 bbl. At the time of his death, Mr. Toner was the oldest employee in the Portland Cement Association from the standpoint of years of service.

Two years after his graduation from college, on August 15, 1906, Mr. Toner was married to Margaret A. Murphy, who, with their son, Arthur C. Toner, Jr., survives him.

Earnestness and sincerity were Mr. Toner's outstanding characteristics. Never did he state a half-truth to accomplish his purpose, and he gave of himself without stint to every task undertaken. He had an analytical mind which caused him to study carefully all phases of a problem in an effort to be certain his conclusions were based upon facts. Mr. Toner's counsel and advice were valued by many who recognized him as a true friend. He was active in several societies and clubs, including the Engineers Society of Western Pennsylvania; the Engineers Club, of Philadelphia; the National Press Club; and the Cosmos Club, of Washington, D. C.

Mr. Toner was elected an Associate Member of the American Society of Civil Engineers on October 1, 1912, and a Member on October 3, 1922.

JOHN JERVIS VAIL, M. Am. Soc. C. E.[1]

Died December 2, 1936

John Jervis Vail, the son of Robert Bruce and Emily (Jervis) Vail, was born at Rahway, N. J., on September 14, 1877. His early education was secured in the public schools of Rahway and at the Rutgers Preparatory School, New Brunswick, N. J. He was graduated from Rutgers University with the degree of Bachelor of Science in 1898, and in 1902 was awarded the degree of Civil Engineer.

From December, 1898, until his death on December 2, 1936, Mr. Vail was connected with the Pennsylvania Railroad Company. Until April, 1900, he was a Rodman in the office of the Assistant Engineer at Jersey City, N. J. He was then transferred to the Chief Engineer's Department, Corps of W. C. Bowles, Engineer of Construction. He became second in rank to Mr. Bowles in 1901, and for the next seventeen years he was in charge in the field. In that time, he supervised the filling, dredging, and erection of bulkheads in New York Bay at the Greenville Terminal; was in charge of the extension of the Pennsylvania Railroad to New York, N. Y.; the elevation of the railroad through Rahway; and important rock excavation work in Jersey City. From 1918 to 1924, Mr. Vail was Assistant Engineer at Meadows Yard, in New Jersey; and was connected with the Valuation Department of the Pennsylvania Company, on appraisals of special structures and on estimates of cost of an automatic electric system, for the New York and New Jersey Power and Light Development.

In 1925, Mr. Vail became Engineer of Construction, Chief Engineer's Department, and supervised the construction of Pier K in Jersey City, the American Railway Express Building, in Long Island City, N. Y., the rebuilding of the Journal Square Station, Jersey City, for the Pennsylvania Railroad —Hudson and Manhattan Railroad Companies.

In 1928, he built the Hackensack River Freight Bridge, the foundations of the State Highway Bridge, and the Hackensack River Passenger Bridge. In 1930, he was engaged in water-front development in Jersey City.

---

[1] Memoir prepared by Earl Reed Silvers, Esq., Dept. of Alumni and Public Relations, Rutgers Univ., New Brunswick, N. J.

In September, 1931, Mr. Vail undertook the preparation of claims for a large reduction of railroad property taxes in the State of New Jersey. Chiefly through his efforts, a reduction in tax assessment of $4 000 000 was obtained, and a reduction in annual tax payment of $100 000. For the next two years, he continued his tax surveys, his work resulting in a total reduction in assessments of $12 000 000.

He was a member of the American Society of Terminal Engineers; New Jersey Professional Engineers; and of Phi Beta Kappa, Zeta Psi, and Theta Nu Epsilon.

A lifelong resident of Rahway, Mr. Vail was continually active in city affairs. He served as a member of the Board of Education for twelve years, and for several years was Vice-President of the Board. As a member of the Common Council, he was the author of the first Building Code established by the City, and was the first to make a five-year plan for city streets and public improvements. In other municipal matters, his knowledge of engineering and experience in public affairs and large construction projects made his service to the City of inestimable value. Throughout his life he took a deep interest in its welfare and fostered many movements which tended to promote its growth along permanent and desirable lines.

Mr. Vail was a member of the Second Presbyterian Church, serving as Deacon for twenty-five years and also on its Board of Trustees. For a long period, he was a Director of the Rahway Young Men's Christian Association, being especially interested in athletic activities and character-building programs. He was President of the Rutgers Club, of Rahway, in its first year of existence, and a member of the Rutgers University Alumni Council.

All who knew him held him in the greatest respect. His rugged honesty, his modesty, his unselfish service to the community, his willingness to assume duties from which he might have excused himself, endeared him to a host of friends. Mr. Vail lived the life of a Christian gentleman; was always considerate of the feelings of others, and always tolerant of human failings and human weaknesses.

On October 19, 1905, he was married, in Rahway, to Anne Evelyn Baumann. He is survived by his widow, two daughters, Anna Marie Vail and Helen Camille (Vail) Hayes, and one son, John Jervis, Jr.

Mr. Vail was elected an Associate Member of the American Society of Civil Engineers on January 4, 1905, and a Member on October 26, 1931.

GEORGE REED WADSWORTH, M. Am. Soc. C. E.[1]

DIED NOVEMBER 1, 1937

George Reed Wadsworth was born in Keene, N. H., on August 22, 1875, the son of Samuel Wadsworth and Ella (Reed) Wadsworth. He was a descendant of Christopher Wadsworth who first came to this country in 1632 and settled at Duxbury, Mass. He attended the Massachusetts Institute of

---

[1] Memoir prepared by Lester D. Gardner, Secretary, Inst. of the Aeronautical Sciences, Inc., New York, N. Y.

Technology, at Boston, Mass., and was graduated with the degree of Bachelor of Science in 1898. He was a leader in undergraduate activities, and at graduation he was First Marshal of his Class, the highest elective honor.

Immediately after his graduation Mr. Wadsworth joined the Engineering Department of the New York Central Railroad Company. He was promoted rapidly from Transitman to Acting Supervisor of Track. In 1901, he was given charge of yards and engine-house layouts, and bridge masonry and renewals, until he became Resident Engineer at Albany, N. Y., in responsible charge of contract work, substructure renewal of the freight bridge across the Hudson River, the passenger station at Troy, N. Y., and car shops at West Albany, N. Y. Coming to New York, N. Y., in 1902, Mr. Wadsworth became Assistant Engineer on terminal improvements in New York City, in charge of the Port Morris Depression, including a 500-ft double-track rock tunnel; 1 500 ft of double-track concrete arch-roof subway; and designs for four-tracking the Electrification Zone. In 1904, he was in charge of the contract work on terminal improvements from Mott Haven, New York City, to Croton-on-Hudson, N. Y.

In May, 1905, he joined the Construction Department of J. G. White and Company, Incorporated, and for two years was engaged in steam and electric railroad construction, irrigation projects, wharves, dams, etc.

In December, 1907, Mr. Wadsworth became Consulting Engineer to the Metropolitan Improvement Commission, Boston, Mass. He prepared a survey which was embodied in the Commission's report to the Commonwealth of Massachusetts, covering the proposed complete unification and operation under joint control of all passenger and freight steam railroad properties and facilities within the Boston Terminal District. He also made a report on the proposed development of Boston Harbor to provide additional water-front facilities.

In June, 1909, Mr. Wadsworth joined the East Boston Company, as Engineer in charge of the preparation of plans and estimates for proposed docks, wharves, railroads, etc., along the water-front of East Boston. From June, 1910, to July, 1913, he was in charge of the design of Peerless automobiles, as Engineering Manager and Chief Engineer of the Peerless Motor Car Company, in Cleveland, Ohio. In 1913, he joined the firm of Gray and Davis, Incorporated, of Boston, which manufactured automobile starting and lighting equipment.

Believing that the United States would soon join the Allies in their struggle with Germany, Mr. Wadsworth decided to acquire some preliminary military training. He attended the Plattsburgh Training Camp in the summer of 1916. This was the first of the Plattsburgh camps and was under the direct supervision of the late Major-General Leonard Wood, U. S. Army. Probably there has never been such a distinguished group of "rookies" as those who joined the First Provisional Training Regiment.

In April, 1917, Mr. Wadsworth became a member of the Staff of Major Henry Souther as a Civilian Engineer in the Aviation Section of the United States Signal Corps. This group was directly in charge of the huge engineering program required to establish hundreds of flying centers for training aviation cadets and construction companies for war service. On June 30, 1917, he was commissioned a Captain in the Aviation Section of the Signal Corps, and on October 3 of the same year he was promoted to the rank of Major.

In October, 1917, at the request of the Chief of the Bureau of Construction and Repair of the United States Navy Department, Major Wadsworth was detailed by the Chief Signal Officer of the Army to the Naval Aircraft Factory, at Philadelphia, Pa. He became Chief Engineer, and under his direction were manufactured many twin Liberty-engined, 7-ton flying boats for patrol and bombing by the Navy. He did an outstanding job of assembling an engineering organization for the factory and in carrying on, under the direction and in consultation with the Bureau of Construction and Repair of the U. S. Navy Department, the engineering, drafting, experimental, and inspection work at the factory.

After his discharge from the Service on December 30, 1918, Major Wadsworth, with a group of aviation engineers, formed The United Engineering Corporation, in New York. This firm was engaged in the development of air transport, airplane manufacturing, and the disposal of surplus war aircraft supplies.

In 1921, he returned to his engineering practice and made several investigations and reports on industrial and economic surveys principally within the Automotive Industry. In 1923, he became interested in the manufacture of electric washing machines and was made Vice-President and General Manager of the Conlon Corporation, in Chicago, Ill.

In 1924 he became an official of the State of New York. Starting with an appointment as Director of the Division of Operating and Planning Research of the Department of Architecture he conducted a study involving basic determination of requirements, diagrammatic layouts, and operating details, involving the future expenditure of $80 000 000 for new State Hospitals for the Insane. Transferring in 1928 to the Department of Correction as Assistant Commissioner he became Superintendent of Prison Industries, in charge of operations of industrial activities in all the correctional institutions of New York State. The production of these prison shops was limited to about twenty lines, but had an annual value of about $2 000 000. He retired from active service on June 30, 1937, due to ill health.

George Wadsworth was regarded by his associates, even from his undergraduate days, as a brilliant student of civic affairs as well as an experienced engineer. His studies in connection with public health and economic trends were an avocation which brought him in touch with many of the forward looking statisticians of the United States. His reports, which he usually preferred to draw and type himself, reflected the skill of presentation which he inherited from his father who during his later life became an amateur maker of many scientific instruments and whose 8-day astronomical clocks are worthy to be placed in scientific laboratories. In his personal relationships, Major Wadsworth attracted the friendship of a wide circle of talented men in many walks of life.

He was a member of the University Club, and the Engineers Club of New York, the Society of Automotive Engineers, and the American Society of Mechanical Engineers.

He was married at Albany, N. Y., to Alice Randie, on April 9, 1902, and is survived by his widow and a son, George Randie Wadsworth, of New York.

Mr. Wadsworth was elected an Associate Member of the American Society of Civil Engineers on November 7, 1906, and a Member on November 8, 1909.

ISAAC STANLEY WALKER, M. Am. Soc. C. E.[1]

Died January 23, 1938

Isaac Stanley Walker was born on July 10, 1883, at Philadelphia, Pa. He was the son of Isaac and Hannah (Singleton) Walker. His father was born in 1840 in Lancashire, England, and came to America in 1861, settling first in Canada, and, later, in Philadelphia.

Mr. Walker received his early education in the Public Schools of Philadelphia, and, later, attended Temple University and Drexel Institute of Technology in that city.

For a period of about five months in 1900, Mr. Walker served as an Apprentice in one of the Survey Districts of Philadelphia. For six months in 1901, he served as a Chainman and Rodman on the Survey Corps of the Cornwall and Lebanon Railroad Company and the Pennsylvania Railroad Company.

From August, 1901, to May, 1910, Mr. Walker was in the employ of the City of Philadelphia, engaged on the Water-Works System. During this time he filled successive positions as Chainman, Rodman, Transitman, and Assistant Engineer. Seven years of this time were spent on the construction and operation of the Torresdale, Belmont, and Queen Lane Filter Plants, and two years on the design and construction of pipe distribution systems.

From May, 1910, to October, 1916, Mr. Walker was engaged as a Staff Engineer with the firm of Hering and Fuller (the late Rudolph Hering, M. Am. Soc. C. E., and the late George Warren Fuller, M. Am. Soc. C. E.) and, later that of Hering and Gregory (the late John Herbert Gregory, M. Am. Soc. C. E.), Consulting Engineers of New York, N. Y. During this period, he served as Designer in preparation of reports, plans, and specifications for the sewerage systems of Vincennes, Ind., and Batavia, N. Y.; for the sewage treatment works of Atlanta, Ga., Batavia, Kings Park, Albany, Mamaroneck, and Larchmont, N. Y.; Chatham-Madison, Orange, Montclair, East Orange, and Trenton, N. J.; Bridgeport, Conn.; and Roland Park, Md.; for water-works and filter plants at Grand Rapids, Mich., Minneapolis, Minn., Montreal, Que., Canada, Zanesville, Ohio, Lynn, Mass., Morgan Estate, New

---

[1] Memoir prepared by a Committee of the Philadelphia Section, Am. Soc. C. E., consisting of W. H. Chorlton, and H. M. Freeburn, Members, Am. Soc. C. E., and C. A. Howland, and L. L. Jenne, Assoc. Members, Am. Soc. C. E.

York, and Charleston, S. C. During 1915 and 1916 Mr. Walker was also an Instructor in Sanitary Engineering in the Extension School Course of Columbia University, in New York City.

From October, 1916, to September, 1918, he was Designing Engineer for sewage treatment works of the City of Philadelphia. During the last five months of this period, he was Division Engineer in charge of this work—a $35 000 000 project.

From September, 1918, to September, 1927, Mr. Walker was General Manager of four water properties—at Chester, Pa., Vincennes, and Greencastle, Ind., and the Delaware Water Supply Company. He was Managing Executive during this period, in charge of all engineering work, including a new filter plant with wharf, intakes, and pumping station at Chester. A valuation of the property of this Company made by him was the basis for a grant of increase in rates by the Public Service Commission of Pennsylvania. During the last two years of this period, Mr. Walker was President of the New Chester Water Company and Secretary of the Vincennes and Greencastle Companies.

From September, 1927, to January, 1930, he was Vice-President and General Manager of the Pennsylvania Water Service Company and the Scranton-Spring Brook Water Service Company, subsidiaries of the Federal Water Service Corporation, with headquarters at Wilkes-Barre, Pa.

From January, 1930, until his death, Mr. Walker had an office in Philadelphia as a Consulting Sanitary Engineer. During this time he visited Russia, as the Representative of a New York Contracting Firm and at the invitation of the Soviet Government, to study and report on a comprehensive plan of water supply, sewerage, and sewage treatment works for the City of Moscow. He also served as an Associate Water Consultant for the National Resources Committee of the United States Government and made a comprehensive study and report on the Delaware River Basin.

Mr. Walker gave freely of his time and effort for the betterment of his profession. By his high qualities of courage, uprightness, and helpfulness, he endeared himself to his associates.

On May 10, 1905, he was married to Lillie Margaret Winner, of Philadelphia. His widow and five children—Edward Stanley, Robert Winner, William Alan, Ruth Evelyn, and Helen Margaret—survive him.

Mr. Walker served as Director, Vice-President, and President of the Philadelphia Section of the Society. He was a member of the American Water Works Association, and served as Chairman of the Four State Section in 1935–1936, and Secretary of the Committee on Water Rates for three years. He was a member of the Pennsylvania Water Works Association, a member of the Executive Committee for four years, and Vice-President for two years. He was also a member of the American Public Works Association, the Pennsylvania Water Works Operators Association, the Pennsylvania Sewage Works Association, and the Engineers Club of Philadelphia.

Mr. Walker was elected an Associate Member of the American Society of Civil Engineers on September 3, 1913, and a Member on January 19, 1923.

JAMES GOOLD WARREN, M. Am. Soc. C. E.[1]

DIED NOVEMBER 2, 1937

James Goold Warren, the son of Joseph and Jane Vail (Goold) Warren, was born at Buffalo, N. Y., on September 12, 1858. He was descended from pioneer stock, the first of his family, John Warren, having arrived in this country from England in 1630. His father, leaving his native State of Vermont, as a young man, took up his residence in Buffalo where he was, for many years, one of its prominent citizens. At the time of his death, in 1876, he was Editor-in-Chief of the *Buffalo Daily Courier*.

James Warren received his early education in the public schools of Buffalo. Later attending Phillips-Exeter Academy, at Exeter, N. H., young Warren planned to continue an education in medicine. This plan was interrupted, however, by his father's death. On July 1, 1877, he entered the United States Military Academy, at West Point, N. Y., from which he was graduated on June 11, 1881, Number 5 in his Class. He was promoted to the rank of Additional Second Lieutenant, Corps of Engineers, U. S. Army.

Lieutenant Warren's first assignment was with the Engineer Battalion at Willets Point, N. Y., from which he was graduated in 1884. During this period he was promoted to the rank of First Lieutenant. From 1884 to 1885, he served as Assistant to the officer in charge of the Chattanooga, Tenn., District, Engineer Department-at-Large. From 1885 to 1887, he was detailed as Instructor in Civil and Military Engineering at the U. S. Military Academy. In 1887 he became Secretary and Executive Officer, Academic Staff of the Engineer School, and Adjutant of the Battalion of Engineers at Willets Point, where he continued on duty until 1891. From 1891 to 1893, he served as Assistant to the officer in charge of the construction of fortifications in New York Harbor.

After a short assignment as Secretary and Disbursing Officer of the Mississippi River Commission, at St. Louis, Mo., Lieutenant Warren became District Engineer at Louisville, Ky., and served as such until 1898. He was promoted to the rank of Captain in 1894.

In 1898, Captain Warren was assigned as District Engineer at Milwaukee, Wis., and, in that capacity as well as that of Engineer of the Ninth Lighthouse District, he served until 1905. He became a Major in the Corps of Engineers in 1901.

From 1905 to 1910, Major Warren was District Engineer at Cincinnati, Ohio, and was also Division Engineer, Central Division, from 1909 to 1910. He was promoted to the rank of Lieutenant Colonel in 1907.

In 1906, he was made a Member of the Mississippi River Commission and served continuously in that capacity until 1919.

---

[1] Memoir prepared by R. B. Perry, Esq., under the direction of Col. E. H. Marks, Corps of Engrs., U. S. Army, M. Am. Soc. C. E.

In 1910, Lt.-Col. Warren became District Engineer at Buffalo, where he had charge of both the Buffalo and Oswego Engineer Districts. He was promoted to the rank of Colonel in 1912 and, in the same year, he was appointed Division Engineer of the Great Lakes Division, in which capacity he supervised all river and harbor activities of the Great Lakes and the St. Lawrence River. He continued to serve concurrently as District Engineer until 1915, and, again, assumed that responsibility from 1917 to 1919.

In 1917, Colonel Warren, by authority of a Joint Resolution of Congress, assumed charge of the "Investigation of Diversion of Water from Great Lakes and Niagara River." This investigation covered the various phases of water diversion, including its effect upon navigation, sanitary and power purposes, and the preservation of the scenic beauty of Niagara Falls and the rapids of Niagara River. The report of this investigation, published in 1920, is regarded as an authoritative text on this all-important subject. The then Senior Member of the Board of Engineers, the late Brigadier-General Harry Taylor, U. S. Army, M. Am. Soc. C. E., commenting for the Board upon Colonel Warren's report, stated:

> "The report is the only comprehensive and thorough investigation of all these subjects ever made and possesses great value, not only from the technical, but also from the very full historic, presentation of the matters with which it deals."

While still Division Engineer of the Great Lakes Division, Colonel Warren, having attained the age of 64 yr, was retired by operation of law on September 12, 1922. He continued to make his home in Buffalo until his death.

During his forty-five years of active service with the Corps of Engineers, Colonel Warren justly earned the reputation of being one of the outstanding members of that organization. As District Engineer at Louisville, Milwaukee, Cincinnati, and Buffalo; during his long term as Engineer of the Great Lakes Division; as a member, for so many years, of the Mississippi River Commission; and as a member of a large number of Special Boards of Engineers, charged with the investigation of a wide variety of problems, he gained invaluable experience and came to be regarded as an authority on all matters pertaining to navigation on the Great Lakes and the inland waterways of the United States.

In 1881, Colonel Warren was married to Sarah Clifton Wheeler, at West Point. Mrs. Warren died in Milwaukee in 1901. A son, Wheeler, and a daughter, Emily Warren, survive him.

Aside from his enviable record as an officer of the Corps of Engineers, Colonel Warren was well known for his unswerving devotion to duty and his unfailing loyalty to those who were associated with him. Commenting on his passing, Colonel John Millis, Corps of Engineers, U. S. Army (*Retired*), M. Am. Soc. C. E., a classmate of Colonel Warren at the Military Academy, stated:

> "I recall the affection and respect which the class of 1881 had for Jim Warren, our first Captain, and the strict fairness and devotion with which

he performed the duties of that youthful but responsible office. These characteristics he continued to display through all of his subsequent career."

Maj.-Gen. E. M. Markham, U. S. Army (*Retired*), M. Am. Soc. C. E., formerly Chief of Engineers, U. S. Army, added the following:

"I pride myself that I analyzed Colonel Warren in early days as a gentle, kindly, characterful man, inflexible of purpose, wishful that he might conceal his downright gentleness. His sturdiness of purpose and character as I observed them, gave me a lifelong inspiration."

In writing of Colonel Warren's career, Gen. Malin Craig, Chief of Staff, U. S. Army, concludes:

"Keenly interested in his profession, with special knowledge of civil engineering as applied to river and harbor improvements, Colonel Warren was on duty for many years in connection with engineering projects on the rivers and lakes of the middle west, and loyally and efficiently performed the duties of an Engineer of the Army throughout his active service covering a period of forty-five years. His death is deeply regretted."

Colonel Warren was elected a Member of the American Society of Civil Engineers on June 24, 1914.

LEONARD CHASE WASON, M. Am. Soc. C. E.[1]

Died April 30, 1937

Leonard Chase Wason was born on August 5, 1868, in Brookline, Mass., the son of Elbridge and Mary Isabella (Chase) Wason. On both the paternal and maternal sides his ancestors were among the earliest of the settlers in the United States.

After his preparatory education, Mr. Wason entered and was graduated from the Massachusetts Institute of Technology, at Boston, Mass., in 1891, with the degree of Bachelor of Science in Electrical Engineering. He began his professional career as a Draftsman in the office of the late Frederick S. Pearson, M. Am. Soc. C. E., of Boston, Consulting Engineer to the Brooklyn City Railway Company, of New York, N. Y., and the Dominion Coal Company, of Boston. For two years Mr. Wason was engaged in design and field supervision. He made all the plans for the Eastern Station, on Kent Avenue, of the Brooklyn Heights Street Railway. He designed a part of a power station at Ottawa, Ont., Canada, and nearly all the improvements made by the Dominion Coal Company for its mines at Cape Breton, Nova Scotia, and its terminals at Montreal, Que., Canada. In 1894, he was Superintendent of Construction of wooden coal-pockets and tower at Wellington (Ont.) Basin. He also designed and built the power plant for coal-handling towers at Hochelaga, Que., Canada.

About this time Mr. Wason became keenly interested in the latent possibilities of reinforced concrete which was then practically in its infancy. In

---

[1] Memoir prepared by S. L. MacMillan, Vice-President, Aberthaw Co., Boston, Mass.

1884 the late Ernest L. Ransome, Affiliate, Am. Soc. C. E., had been granted a United States patent applying to the use of "iron bars, bands, or hoops, twisted, so as to form a continuous bond with the concrete, in which they are permanently imbedded", and during the following ten years a few structures of reinforced concrete had been built in California. In 1894, Mr. Wason, with Messrs. William Hartley Dennett, and Ross F. Tucker, the latter holding a license from the Ransome and Smith Company, of San Francisco, Calif., granting to him the use of various patents for concrete construction in the States of Massachusetts, Rhode Island, and part of Connecticut, associated themselves together for the purpose of forming a company to engage in construction work, and incorporated the Aberthaw Construction Company under the laws of the State of Maine. This name was later changed to Aberthaw Company, and a corporate charter was issued to the Company by the Commonwealth of Massachusetts.

During the first year, Mr. Wason served as Director and Engineer of the Company, but was elected President and Treasurer in 1895, which offices, together with that of Director, he held continuously until the time of his death.

As he devoted practically his entire business career to the development and management of this Company and lived to see it grow from a very small and obscure beginning into one of the leading construction companies in the United States, the following notes regarding the derivation of the name "Aberthaw" may be of interest.

As previously stated, Mr. Wason had become enthused over the possibilities of concrete. He and his associates were familiar with the experiments carried on by John Smeaton in 1756 when he was engaged in rebuilding the Eddystone Lighthouse off the English Coast. This lighthouse was built in an exposed and dangerous location where the difficulties of construction were enormous and where terrific storms not infrequently lashed the work with furious severity. Smeaton, therefore, deemed it necessary to use a cement that would be capable of withstanding the influence of sea water and possessing also the capacity of resisting the mechanical action of violent storms. With painstaking care he set out to discover, if possible, a cement that would fulfill these requirements. After numerous tests with the different materials available to him, and concerning which he has left detailed and complete accounts, he determined that all the limes which could set under water were obtained from the calcination of such limestone as contained a large proportion of clay in their composition, and it is universally acknowledged to-day that Smeaton originated the science of water cements. He demonstrated that the real cause of hydraulicity of cement was due to an argillaceous admixture and that the previously held theory that the purest and hardest limestone was the best material for such purposes was incorrect.

Of the different limes with which he experimented, a blue lias lime from Aberthaw, a little sea-coast town in Glamorganshire, Wales, when mixed with various proportions of tarras greatly excelled any of the other mixtures. Its behavior under water was satisfactory, and it continued to harden for months.

Using a cement compounded of this Aberthaw lime and of puzzolana brought from Civita Vecchia, near Rome, Italy, Smeaton constructed the Eddystone Lighthouse, which was to endure for many years as a beacon not only to storm-tossed sailors, but also to those who were endeavoring through research and experimentation to increase the technical knowledge pertaining to the Building and Engineering Professions. That the base of this lighthouse still stands is eloquent testimony to the ability of its constructor and the efficacy of the material with which he worked.

In his accounts, he states that by the use of Aberthaw lime and puzzolana he did not doubt "that they would make a cement that would equal the best merchantable Portland Stone in solidity and durability".

In 1824, Joseph Aspdin, a bricklayer of Leeds, England, was granted a patent for his invention of "an improvement in the Modes of Producing an Artificial Stone". He gave the name "Portland Cement" to the product and was the inventor of that application of the name. While he maintained a great deal of secrecy concerning the exact proportions of the various ingredients contained in the cement he manufactured, it is believed that he also made extensive use of "Aberthaw" lime in his product. It, therefore, was a happy inspiration and the result of studious research into the early history of the materials with which Mr. Wason and his associates planned to work and specialize, rather than mere chance that suggested the adoption by them of the name, "Aberthaw", as one peculiarly fitting to their enterprise. Under Mr. Wason's guidance and direction the Aberthaw Company was the pioneer company in New England to specialize in designing and building in reinforced concrete, later extending its activities to all types of construction work. He conducted extensive experiments and research in concrete materials, their uses, and application, and originated many devices useful in construction work.

Among the early noteworthy structures built by the Aberthaw Company under his direction were the Harvard Stadium; Fall River, Mass., Public Library; and the Attleboro, Mass., water stand-pipe, which at the time it was constructed, was the largest reinforced concrete stand-pipe in the world. During the World War, the Company built structures costing many millions of dollars, including buildings for the Winchester Repeating Arms Company, at New Haven, Conn., the Victory Plant of the United States Navy Department, at Squantum, Mass., and many other projects of similar nature. In more recent years the Company constructed the Christian Science Publishing Building, at Boston, at a cost of $4 000 000; re-built the Provident Institution for Savings Bank Building, at Boston; constructed the State Pier at Portland, Me.; the reinforced concrete grandstand, capable of seating 13 000, at Suffolk Downs, East Boston, Mass.; the Converse Memorial Building for the New England Baptist Hospital, at Boston; the Hanchett Memorial Building for the Lowell General Hospital, at Lowell, Mass., and numerous other projects.

During the period of Mr. Wason's Presidency, the Aberthaw Company built structures totaling more than $100 000 000 in value, and ranging geographically from the Gaspé Peninsula in Canada to the British West Indies, and from the Atlantic Coast to the Pacific Coast.

In 1905 Mr. Wason assisted in organizing the Federal Mutual Liability Insurance Company, and served as a Director in that Company, and, later, as a Director in the Lumberman's Mutual Casualty Company, of Chicago, Ill.

He was one of the very early members of the American Concrete Institute and served as President of that organization in 1915 and 1916. He was a donor of the American Concrete Institute Wason Award for research on concrete; also of the Wason Medal for the most meritorious paper on the subject presented annually.

He assisted in the founding of the Associated General Contractors of America, Inc., and served as Vice-President of the New England Branch of that organization. Upon learning of Mr. Wason's death, Mr. Edward J. Harding, Managing Director of the Associated General Contractors of America, Inc., wrote to the Aberthaw Company:

"Word of Mr. Wason's passing was received by the Association while its Executive Board was in session in Washington. All members present were visibly affected by this information and the Board, in behalf of the Association, endeavored to express its deep feeling by resolution. This resolution is here transmitted with the request that you convey these sentiments of the Association to the members of his family and to his business associates.

"RESOLUTION

Adopted by the Governing Board of The Associated General Contractors of America, Inc., May 1, 1937, Washington, D. C.

"With deep sorrow the Governing Board of the Associated General Contractors of America, in meeting assembled at Washington, D. C., May 1, 1937, learns of the passing of Leonard C. Wason on April 30, 1937. This Association, through its Governing Board, expresses its appreciation of his deep interest and activity in its founding and his continuous loyalty to its principles; now, therefore, be it

"*Resolved*, that the members of the Associated General Contractors of America record their positive knowledge, individually and collectively, that he has left to this Association and the Construction Industry a heritage in the record of his noble and unselfish life; his technical ability and counsel; his sterling character and high conception of duty, and his unfailing kindness have inspired the respect, admiration and affection of his associates and friends on whom his passing has produced profound grief and sorrow, with a realization that the memory of his character and accomplishments will serve as an incentive to those who will carry forward the constructive work for which he so tirelessly labored; and be it further

"*Resolved* that this expression be spread upon the permanent records of the Associated General Contractors of America and that copies be sent to his family and business associates."

In 1901, Mr. Wason prepared a Hand Book for the use of engineers, architects, and builders, giving data relative to reinforced concrete construction. He also wrote numerous articles for technical societies and the technical press concerning the design of reinforced concrete structures, the physical properties of buildings materials, methods and equipment for use in construction, cost accounting, estimating, etc.

He was awarded the Phebe Hobson Fowler Professional Award by the Society for meritorious achievement for first honor (1929), as a recognition of his work as Chairman of a Committee of the Northeastern Section which developed the Code of Practice adopted by the Society. For the Society, he served as a member of the Joint Committee on Specifications for Concrete and Reinforced Concrete. He also represented the Society as a member of the Sectional Committee working on the development of a Construction Safety Code sponsored by the American Standards Association. He was always keenly interested in the subject of accident prevention, and felt that every reasonable precaution should be taken that would ensure safe working conditions for employees. It was, therefore, a source of great pride to Mr. Wason when, in 1933, the Aberthaw Company won the Goble Contest for that year. This contest is held annually under the auspices of the Associated General Contractors. The award is made at the Annual Convention of the Associated General Contractors and consists of a sterling silver cup offered as a prize to the member (company) having the best accident prevention record during the contest period on man-hours lost against man-hours worked. Typical of his sincere desire to prevent accidents and the grief and loss caused to the family of the person injured is the notice Mr. Wason had printed on each pay envelope issued by Aberthaw Company which read:

> "Any man working on a runway or scaffold, or in, upon, or in connection with any ways, works or machinery which he considers unsafe or dangerous, must report the same to the foreman in charge. If the foreman fails to remedy the defects, you should refuse to work upon or near the place considered unsafe."

He was interested in the welfare of his workmen and always ready to lend his time to their problems and financial assistance in needy cases.

He was a member of the American Society for Testing Materials, the American Society of Mechanical Engineers, the Boston Society of Civil Engineers, in which body he held office as Director and Vice-President. He also belonged to Chi Phi Fraternity, the Algonquin, and Boston City Clubs, the Fraternity Club, of New York, and the Boston Chamber of Commerce.

Mr. Wason had always been active in civic affairs, having been Chairman of the Brookline Planning Board; a member of the Board of Appeal (Building Department); a member of the Brookline Town Meeting; and a member of the Boston Noise Abatement Committee. He was a life member of the Massachusetts Charitable Mechanics Association since 1928; a Director of the Master Builders Association of Boston during 1925, 1926, and 1927, and a member of the Business Men's Vocational Board of the College of Business Administration of Boston University. He served as a Director and as a member of the Executive Committee of the Massachusetts State Chamber of Commerce, and was also a member of the United States Chamber of Commerce. His favorite outdoor diversion was golf.

For many years prior to his death he had been a member of The First Church of Christ Scientist, in Boston.

Mr. Wason was a man who never sought public prominence, although he gave generously of his time to civic affairs and served on many committees.

He was always very much interested in pending legislation and firmly believed it was the duty of citizens to advise their legislative representatives concerning their views on current bills under consideration for enactment and to appear at public hearings for the purpose of either supporting or opposing measures of importance to the community. He was a liberal contributor to charitable enterprises.

He insisted on absolute honesty in all his transactions and maintained that a reputation for honesty and integrity was the most valuable asset that an individual or a company could possess. He possessed a very even disposition and no matter how trying or provocative a situation might be he never gave outward evidence that he was perturbed. He gave full consideration to all matters that came to his attention for decision and never rendered a hasty judgment. He never gave any indication of any knowledge of fear. He never spoke disparagingly of any one. He was abstemious in his habits and furnished an example of honest and upright living to his friends and associates.

Mr. Wason was imbued with a spirit of cheerfulness. This, together with a kindly nature, he manifested daily in his association with his employees. He always looked on the brighter side of things and maintained an optimistic attitude even during the trying period of the depression when the outlook for the Construction Industry was very uncertain.

He was twice married: First, on October 8, 1896, to Harriet C., daughter of James D. K. Willis, of Boston. Mrs. Wason died in 1915, leaving four children, Elbridge, Alfred Boyd, Raymond, and Lawrence Willis Wason. On June 24, 1916, Mr. Wason was married to Mrs. Annie B. (Atwood) Redlon, widow of Charles H. Redlon, of Portland, Me., who survives him.

Mr. Wason was elected an Associate Member of the American Society of Civil Engineers on April 3, 1901, and a Member on April 1, 1903.

SAMUEL C. WEISKOPF, M. Am. Soc. C. E.[1]

DIED DECEMBER 20, 1936

Samuel C. Weiskopf was born in New York, N. Y., on September 17, 1860. He was the fourth of six children, five boys and a girl. Most of his childhood was spent in Milwaukee, Wis., to which city the family moved when he was about twelve years old.

After the usual preparatory schooling he entered the University of Michigan, at Ann Arbor, Mich., and was graduated from the Engineering Department in June, 1882, with the degree of Bachelor of Science. Immediately thereafter he obtained employment as a Draftsman in the office of Rust and Coolidge, Bridge Builders, in Chicago, Ill., and fifteen months later received an appointment as Assistant Engineer in the office of the Chief Engineer of the Chicago, Milwaukee, and St. Paul Railroad Company. As such he assisted in the design of bridges and other structures until the fall of 1885, when he was put in charge of the shop work for all bridges of the road. By 1888, Mr. Weiskopf had become known as an authority, reporting on bridges for the Richmond and Allegheny Railroad, Western Railway of Alabama, and Kanawha and Ohio Railway Companies. The Cleveland and Mahoning Valley Railway Company had adopted his designs for roundhouses in competition with its own.

---

[1] Memoir prepared by William H. Yates, and John W. Pickworth, Members, Am. Soc. C. E.

In 1898, Mr. Weiskopf changed his headquarters to New York City, and in private practice began to devote himself more to building than to bridge work. At that time cast iron was used generally for columns, and his details of bases and beam connections were adopted as standard and published, in 1901, by the American Bridge Company. He had a genius for simplification and standardization, and that helped him to attain a position of pioneering leadership in an ever-widening field of high building construction.

Quickly and thoroughly he adopted the philosophies of this new work. He realized that here he had to accommodate the engineering with safety to architectural requirements, and his successful accomplishment of this aim, together with a natural modesty, perhaps accounts for the fact that he did not receive even greater public recognition than he did. His devotion to the art of engineering made him take the greatest personal satisfaction in having the architecture of the finished building unspoiled by an obtrusive skeleton.

He retained the boldness of the bridge builder, and as he designed bigger and higher structures he did not hesitate to execute longer and heavier spans in order to create large rooms unobstructed by column supports. He was expert in all phases of building design, was one of the first to adopt the pneumatic caisson for foundations, and in intricate wind-bracing he contributed valuable details, making possible the elimination of unsightly brackets and braces without the sacrifice of rigidity. He had the vision to perceive that it was possible to erect a high frame without using diagonals but with the joints between columns and beams adequate in strength and stiffness, concealed within the depth of the floor and the width of the column. The Trinity Building, in New York City, was one of the early designs embodying this principle. Many other buildings in the Wall Street District gave him an opportunity to develop and apply this conception. Some of the most prominent buildings in that District are: The City Investing Building; Adams Express Building; American Telephone and Telegraph Building; The Bank of America; and on three corners of Wall and Broad Streets, the Bankers Trust Company, the New York Stock Exchange (where 24 stories are carried by trusses over the Board Room), and the Morgan Bank, part of which he later spanned to carry 33 stories of the Equitable Trust Company Building, the air above the bank having been leased for a long period of years.

Farther up-town in New York City, the American Radiator Building and the *Daily News* Building bear the stamp of his work. He designed many buildings in other parts of the United States, particularly in Pittsburgh, Pa., where the Mellon National Bank and the Gulf Oil Buildings stand. The

36-story narrow tower of the Travelers Insurance Company Building, in Hartford, Conn. (supported partly on cantilever trusses over an existing structure, and the highest building in New England), was perhaps one of the most difficult and involved problems in wind-bracing ever to be presented to an engineer. It is one of Mr. Weiskopf's most daring and successful accomplishments.

In 1920, he took his Principal Assistant into partnership to form the firm of Weiskopf and Pickworth and three years later, just after the earthquake disaster in Japan, he was called there to advise the Mitsui Bank on the problems of designing to withstand such shocks. The design of the main building in Tokyo and of four branch banks in other Japanese cities was the result. These structures attracted world-wide attention as the first thorough attempt at a solution to such a bracing problem, and were the crowning achievement to a career devoted to intricate structural design.

His kindly nature in all matters not only encouraged the young engineers who came in contact with him, but proved most helpful to the less experienced. His mind was always open to suggestions of his fellow engineers, but before any acceptance of such he would satisfy himself that the fundamental principles he so strongly advocated were not violated. He was so thorough in his analysis of any engineering problem that the practical execution of his design never failed to produce the desired results.

Mr. Weiskopf was for many years an active member of the Engineers Club in New York City, but he always found his greatest pleasure in his family life. In his later years he traveled extensively in Europe for recreation, and, in 1934, he retired from active practice to his home in Florida, where he died after a long illness.

His kind mildness of manner, his modesty, and the simple honesty of his thinking, endeared him to all who knew him, but denied him honors he deserved but never aggressively sought. He is survived by his widow, Stella C. Weiskopf, and his two sons, Walter H. Weiskopf, M. Am. Soc. C. E., who is active as a partner in carrying on the practice of his father's firm, and Edward F. Weiskopf, Assoc. M. Am. Soc. C. E.

The Structural Engineering Profession can rightfully be thankful that Samuel C. Weiskopf was a member of it.

Mr. Weiskopf was elected a Junior of the American Society of Civil Engineers on May 7, 1884, and a Member on December 5, 1888.

WILLARD OLNEY WHITE, M. Am. Soc. C. E.[1]

DIED MAY 19, 1937

Willard Olney White was born in Western, N. Y., on September 15, 1876. He was the son of the late Franklin and Harriet (Olney) White. His forebears were early settlers of Rhode Island who migrated to New York State and settled in the rich farming country there about 1800.

---

[1] Memoir prepared by Chester M. Lingle, Esq., assisted by Albert J. Opperman, Esq., Uniontown, Pa.

As a boy Mr. White attended public school in Western and, subsequently, prepared for college at Cazenovia Seminary, Cazenovia, N. Y., from which he was graduated in 1896. He then entered the Engineering School of Cornell University, at Ithaca, N. Y., and was graduated in 1900 with the degree of Bachelor of Science.

From June to September of that year, he was engaged as a Chainman and Rodman for the Central Railroad Company of New Jersey. He then entered the Engineering Department of the American Coke Company, at Edenborn, Pa., as a Draftsman, later, becoming Chief Draftsman for the Company. This work consisted of the development of 9 500 acres of Pittsburgh coal, requiring six shafts, 800 coke ovens, houses, water system, streets, and all plant buildings.

In May, 1901, Mr. White joined the Engineering Department of the H. C. Frick Company, as Assistant Division Engineer, at Leckrone, Pa. Two years later, in May, 1903, he was transferred to the General Office of the same Company at Scottdale, Pa., in charge of design and construction of buildings, trestles, coke ovens, arches for permanent haulage ways in mines, mechanical haulage devices, etc. He also supervised a part of the construction of arch lining and permanent track arrangement for shaft bottoms at the Lambert and Ranes Mines.

From January to June, 1904, he served as a Draftsman in the Engineering Department of the Middle Division of New York State Canals, at Syracuse, N. Y. He was then appointed Assistant Engineer of the New York State Barge Canal, in charge of the Drafting Office, preparing plans and estimates for the canal construction. From February, 1905, to March, 1907, he was in charge of the Drafting Office on Barge Canal Residency No. 5, at Rome, N. Y., where he supervised the preparation of contract maps and estimates of quantities for 25 miles of canal.

During this time he qualified as Resident Engineer, but before receiving his appointment Mr. White accepted a position as Chief Engineer of the Tower-Hill Connellsville Coke Company, at Republic, Pa. As such he was in full charge of the construction of two coke plants, involving the sinking of four shafts, the installation of all power equipment, the building of tenement houses, the development of mines, and the construction of 680 coke ovens, together with railroad connections. At this time he also patented a door for coke ovens which the Tower-Hill Company used on many of its new ovens.

In October, 1910, Mr. White opened an office in Uniontown, Pa., as a Consulting Civil and Mining Engineer. Although his practice was successful, he preferred construction work, and in May, 1916, he entered the Engineering Department of the Youngstown Sheet and Tube Company, at Hubbard, Ohio, in charge of construction. In December of the same year he was made Chief Engineer of the Buckeye Coal Company, at Nemacolin, Pa., a subsidiary of the Youngstown Sheet and Tube Company. This work consisted of the complete development of 8 600 acres of Pittsburgh coal for a daily production of 6 000 tons. The plant at Nemacolin is one of the finest in the United States, with all modern improvements in the town plan. The mine with its concrete lined shafts, slope, and shaft bottom headings, required the most exacting detail and advance thinking and planning for such a large daily tonnage of coal.

In May, 1918, Mr. White was appointed Chief Engineer for W. J. Rainey, Incorporated, in Uniontown. This Company operated eight coal mines. The development of new mines and the modernization of old ones were under his supervision. He remained with this Company until his retirement in April, 1936.

Mr. White was a splendid citizen of unquestioned integrity. He won the respect of all who knew him, and made real friends among all the types of people with whom he came in contact. These friendships, once made, were lasting because his own high standards inspired confidence and loyalty in others.

Due to the exacting nature of his work, he had little time for recreation. Although fond of good music and books, his greatest joy was in fishing, and he never missed an opportunity to avail himself of this sport. He was a keen observer and student of Nature and spent many vacations in the Adirondacks where he could fully enjoy the woods and streams which he loved so much. In later years he turned to water-color painting as a hobby, and his years of detailed study of Nature showed in the accuracy and beauty of his painting.

Mr. White was a member of the Rod and Bob Club, of Cornell University; a member of the Presbyterian Church; and for many years an active Rotarian. He was also a member of the American Institute of Mining and Metallurgical Engineers.

In June, 1904, he was married to Mary Ann Neff, a daughter of Dr. and Mrs. George W. Neff, of Masontown, Pa. She and one daughter, Mary (White) Hubbard, survive him.

Mr. White was elected an Associate Member of the American Society of Civil Engineers on April 3, 1907, and a Member on March 3, 1911.

WINTER LINCOLN WILSON, M. Am. Soc. C. E.[1]

DIED JULY 15, 1937

Winter Lincoln Wilson was born in Cecil County, Maryland, on December 29, 1866, the son of John Emory and Hannah Dutton (Broomall) Wilson. His early education was obtained in the public schools of Elkton, and the Elkton Academy, prior to entering Lehigh University, at Bethlehem, Pa., from which he was graduated in 1888 with the degree of Civil Engineer.

Following his graduation Mr. Wilson entered the employ of the Pennsylvania Railroad Company in various capacities and was connected with numerous preliminary surveying and construction projects then being carried on by that Company. In 1891, he was engaged as a Topographer (Corps No. 3) by the Intercontinental Railway Company, making surveys through Ecuador and Peru, in South America, in entire charge of the topography. Returning in 1892 to Washington, D. C., he completed the mapping from Quito, Ecuador, to Lake Titicaca, Peru. Later, he took charge of completing maps and profiles of the Intercontinental Railway surveys from Quito, Ecuador, to Punta Arenas, Costa Rica.

---

[1] Memoir prepared by a Committee of the Lehigh Valley Section, consisting of S. A. Becker and M. O. Fuller, Members, Am. Soc. C. E.

His experiences in surveying work impressed Mr. Wilson with the need of a knowledge of law and legal matters. Consequently, for several years he read and studied law, and, in 1894, was admitted to the bar in his home County.

Until 1896, his work as Assistant to Construction Engineers on various projects of the Pennsylvania Railroad Company gave him opportunities to enrich his experience in railroad work.

From 1896 to 1898 he had charge of mapping from the notes of thirteen years of field work by the Guatemala Commission for the Guatemala-Mexico boundary surveys.

Mr. Wilson was appointed Instructor in Civil Engineering at Lehigh University in 1898. During this appointment, he continued his theoretical studies and received the degree of Master of Science in 1901. His practical connections included a study of the virtual profile of the Lehigh Valley Railroad from Jersey City, N. J., to Mauch Chunk, Pa. In 1901, he accepted the headship of the Department of Civil Engineering at Tulane University, at New Orleans, La., which he held until 1904 when he returned to Lehigh University as Assistant Professor of Civil Engineering. Upon the retirement of the late Mansfield Merriman, M. Am. Soc. C. E., in 1906, Professor Wilson was appointed Acting Head of the Department, and, in 1907, was appointed to the Chair of the J. T. Stuart Professorship of Railroad Engineering, which position he held until he was obliged to retire on account of ill health in 1935. He was then made Professor Emeritus of Railroad Engineering. He was the author of the book entitled "Elements of Railroad Track and Construction," published in 1908.

Professor Wilson was active in practical engagements of civil engineering as well as civic government. He served as a member of the old Borough Council of Bethlehem for many years. As Chairman of the Street Committee, he was responsible for the permanency of street improvements made at the time. He served on a special committee appointed to study the water supply and was instrumental in increasing and improving the source of supply and the installation of an improved distribution works, the greater part of which is still a valuable and efficient part of the water supply system for the city. He took part in the campaign, and was connected with some of the preliminary work, which eventually resulted in the building of the city's "Hill-to-Hill" Bridge. He was active in the work of the reconstruction of the Broad Street Bridge and the widening of its approaches.

Professor Wilson served on various Faculty committees and was repeatedly formulating and supporting policies tending toward the improvement of existing conditions. As a member of the Lehigh University Athletic Association for many years, and also as its Secretary, he did much to improve and protect the physical and athletic training of the students.

He was Superintendent of Construction of the Alumni Memorial Building erected on the campus to serve the various Administration units of the University.

Professor Wilson was identified with numerous organizations and clubs, namely: Lehigh University Alumni Association; University Home Club; Bethlehem Club; Saucon Valley Country Club; Lehigh Country Club; and various others. He was a member of the American Society of Military Engineers; Society for the Promotion of Engineering Education; American Railway Engineering Association; and a Registered Civil Engineer and Surveyor.

He became a member of the Masonic Fraternity prior to coming to Bethlehem, and was affiliated with the Bethlehem Lodge No. 283, F. and A. M., being a Past Master; Zinzendorf Chapter No. 216, R. A. M., being a High Priest; Bethlehem Council No. 36, R. S. M.; Lehigh Consistory, A. S. S. R.; and a Charter Member of Bethlehem Forest No. 61, Tall Cedars of Lebanon.

He was a member of the staff engaged in the vocational training of enlisted men at Camp Coppee during the World War. He also volunteered on the Committee of Advisers to registrants for service overseas, and was a member of the Bethlehem Home Guards.

Professor Wilson was twice married. His first wife was Mary Mahala Turner, of Baltimore, Md., who died in 1928. They had two sons who survive him: Maris Wright Wilson, and Captain Alvin Turner Wilson, U. S. Army. His second wife, Mrs. Ann Fenner Anderson, preceded him to the grave in 1932.

Professor Wilson had a clear and vigorous mind which made him effective as a teacher and valuable as a counselor in many matters. He was generous, and had a warm friendship for students and colleagues. He was a patriot in his unselfish loyalty to his country, a doer of good deeds, and a timely help to the practical success of many a fellow alumnus.

Professor Wilson was elected a Member of the American Society of Civil Engineers on May 1, 1901.

ALLAN SHELDON WOODLE, JR., M. Am. Soc. C. E.[1]

Died March 20, 1937

Allan Sheldon Woodle, Jr., was born on March 17, 1878, in Altoona, Pa., the son of the Rev. Allan Sheldon Woodle, rector of St. Luke's Episcopal Church, at Altoona, and Abby Cary (Tisdale) Woodle. His early education was received in St. Paul's School, Concord, N. H., from which he was graduated in 1895. He attended Trinity College in Hartford, Conn., from which, in 1899, he was graduated with the degree of Bachelor of Arts. In the spring and summer of 1898, he worked as Chainman for the Pennsylvania Railroad Company.

---

[1] Memoir prepared by C. B. Rose, Works Mgr., Baldwin Locomotive Works, Philadelphia, Pa.

Immediately upon his graduation from college, Mr. Woodle secured a position with the Pennsylvania Railroad Company, and was engaged until May, 1902, as a Rodman, Leveler, and Transitman in the Construction Department. He was then transferred to the Maintenance-of-Way Department and worked as Assistant Supervisor at Greensburg and Mifflin, Pa., for more than a year.

In May, 1903, he was employed by the Baltimore and Ohio Railroad Company as Assistant Engineer of Maintenance and Way. He was transferred after a year to Philadelphia, Pa., as Assistant Division Engineer. In August, 1905, he went to Wheeling, W. Va., where, until September, 1906, he served as Division Engineer.

During the next ten years Mr. Woodle was employed as Assistant Plant Engineer and Engineer in Charge of Construction for The Baldwin Locomotive Works, at Eddystone, Pa., where much large construction was under way to house the manufacture of locomotives.

For two years during the World War, Mr. Woodle served as Engineer of Plant for the Eddystone Ammunition Corporation. He then returned to The Baldwin Locomotive Works, with which Company he remained, as Plant Engineer, until his death.

Mr. Woodle was married to Alice Jenner, on August 30, 1911, and they made their home in Narberth and Ridley Park, Pa. He died on March 20, 1937, of pneumonia, after a short illness, and is survived by his widow and three children, Allan Sheldon, III, Abby Jane, and Mary Elizabeth.

He wrote a number of articles which were published in various magazines, on the subjects of reinforced concrete design and on steam-boiler efficiency.

Mr. Woodle will be remembered by all who knew him as a man of extraordinarily gracious disposition. His manner was quiet and dignified, and few people ever saw him upset or ruffled. He was a scholarly man and a good and efficient business executive.

He was a member of the Concrete Institute Club, and of the Psi Upsilon Fraternity.

Mr. Woodle was elected an Associate Member of the American Society of Civil Engineers on July 9, 1906, and a Member on March 12, 1918.

ROBERT JOSEPH HENDERSON WORCESTER, M. Am. Soc. C. E.[1]

Died September 27, 1937

Robert Joseph Henderson Worcester was born in Boston, Mass., on December 8, 1882, and died, after a protracted, distressing illness, at Elizabethton, Tenn.

---

[1] Memoir prepared by J. R. Worcester, Hon. M. Am. Soc. C. E.

He became an engineer without the benefit of a technical education, through his ability to acquire and retain information and an ambition to improve every opportunity for learning. He was never satisfied to " rest on his oars," but was always wide awake and on the lookout for instruction. He had the benefit of a Correspondence School course in mapping and surveying, and was able to learn much by private reading. His only schooling was in primary schools near Newark, N. J., and in the United States School for Naval Apprentices, at Newport, R. I.

At the age of eighteen, Mr. Worcester enlisted as a Private in the United States Army, and was assigned to the 11th Cavalry, then being organized at Fort Myer, Virginia. In 1902, this unit was sent to the Philippine Islands, where he served for three years, as Private, Corporal, and Sergeant. Upon his discharge, he returned to Newark and found work as a Foreman for the Newark Paving Company.

In January, 1905, he entered the employ of Westinghouse, Church, Kerr, and Company, with which he was associated for about eight years, in various capacities, such as Rodman, Transitman, Foreman, Inspector, Party Chief, Engineer, Assistant Superintendent, Office Assistant, Computer, etc. The work included street railway construction and equipment, and an investigation of a water power site on the Kootenai River in Northwestern Montana. This investigation required making cross-sections of the river bottom and measurements of stream flow under great difficulties, owing to the swiftness of the current and the extremely cold weather. During this period, he also had some experience in concrete construction, as Foreman for the Eastern Concrete Construction Company, and the Aberthaw Company.

In May, 1913, Mr. Worcester was engaged by the Town of Concord, Mass., as Engineer and Superintendent of Roads and Bridges, which position he held, except during the World War, until May, 1920.

He was instrumental in organizing the " Concord Minute Men," and in August, 1917, he attended the Second Officers Training Camp, at Plattsburgh, N. Y. In December, 1917, he joined the 151st Depot Brigade, then stationed at Camp Devens, Massachusetts, as Brigade Engineer and Utilities Officer, and was in charge of drainage, road construction, and buildings, until June, 1918, when he was sent to France, having received a commission as First Lieutenant of Engineers. With the 317th (Rainbow) Division, he was in the St. Mihiel Salient, his work consisting largely in the construction of trenches, roads, and bridges. He was cited and received the Purple Cross for building a pontoon bridge, in the night and without tools, in record time. After the Armistice he was with the Army of Occupation on the Rhine until May, 1919. At his discharge he became a Captain in the Officers Reserve Corps, but was obliged to resign as he was unable to attend the summer encampments.

In May, 1920, Mr. Worcester joined the organization of Lockwood, Greene and Company, which he served as Resident Engineer on various projects throughout the country. Among these were: A cotton mill and steam power plant at Somersworth, N. H.; and a hydro-electric and cotton mill at New Braunfels, Tex. He was the Works Manager on the construction of the first worsted mill south of the Mason and Dixon Line, at Duncan, S. C., where a steam plant and a mill village were also built. In 1925, he had charge of the Charlotte, N. C., Office of the Company, from which he was transferred to Johnson City, Tenn., to supervise the construction of the rayon plant of the American Bemberg Corporation, and, later, at the same place, the plant of the American Glanstoff Corporation.

Upon the completion of these plants, Mr. Worcester entered the service of these Companies, as Plant Engineer, Consulting Engineer, and, finally, in 1930, as Personnel Director for the North American Rayon Corporation, which position he held until his death.

Mr. Worcester was beloved and respected by all who knew him. He was interested in all social and athletic activities; a leader of the Boy Scouts, from which organization he received the Silver Beaver decoration; a devoted member of his Church; a Past-President of the local Rotary Club; and a Director of the Chamber of Commerce of Elizabethton, where he had his residence. He was also a member of the Boston Society of Civil Engineers.

He was married, in 1909, to Sharlot Groshans, of East Liverpool, Ohio, who survives him. They had no children.

Mr. Worcester was elected a Member of the American Society of Civil Engineers on January 19, 1925.

DAVID LeROY YARNELL, M. Am. Soc. C. E.[1]

DIED MARCH 9, 1937

David LeRoy Yarnell, the son of Ervin and Catherine (Countryman) Yarnell, was born at Storm Lake, Iowa, on January 13, 1886, and died on March 9, 1937, of coronary occlusion, after spending the day at his office.

He was educated in the public schools in Iowa, was graduated from Iowa State College, at Ames, Iowa, in 1908 with the degree of Bachelor of Civil Engineering, and received the professional degree of Civil Engineer from that College in 1916. In 1926, he was awarded the degree of Master of Science in Hydraulic Engineering by the State University of Iowa, at Iowa City, Iowa.

The early years of Mr. Yarnell's professional life were spent in the field, chiefly in connection with drainage engineering. In April, 1909, he was appointed Assistant Drainage Engineer in the United States Department of Agriculture, and was engaged on preliminary investigations and designs of drainage works in Nebraska, Kansas, Virginia, North Carolina, Oklahoma, and Arkansas. Advancing to the grade of Drainage Engineer in February, 1911, he was placed in charge of surveys and designs of drainage systems, technical investigations on run-off from drained land, and investigations of ground-water in tiled land. He was a member of the Board of Engineers appointed to prepare a plan for the Cypress Creek Drainage District, in Arkansas, and during this period he also surveyed and prepared plans for reclamation work at Pond Creek, Ky.

---

[1] Memoir prepared by S. M. Woodward, L. A. Jones, and F. T. Mavis, Members, Am. Soc. C. E.

In 1916, Mr. Yarnell became Senior Drainage Engineer of the U. S. Department of Agriculture, and it was then that he embarked upon his career in research which was to bring him world-wide recognition for careful, systematic, and authoritative contributions to experimental hydraulics.

During 1916 and 1917, at Arlington, Va., he conducted systematic tests on the flow of water in drain-tile and vitrified pipe in sizes from 4 in. to 12 in. in diameter. The report of these studies [2] foreshadowed the pattern of many of his later reports, and it is one of his most widely known publications. More than 800 distinct tests were conducted with an unrelaxing attention to detail which characterized all his work. No other report on this subject has commanded greater confidence from hydraulic engineers.

In 1922, hydraulic investigations were undertaken co-operatively by the U. S. Department of Agriculture and the State University of Iowa, and Mr. Yarnell was placed in charge of these investigations at Iowa City. His first major research at the Hydraulics Laboratory was on the flow of water through culverts,[3] and during a 2-yr period 3 300 tests of culverts ranging in size from 12 in. in diameter to 4 ft square were conducted at the Laboratory. He employed Senior and Graduate Engineering Students to assist him with the details of this investigation, and from that time until his death, his kindly influence and encouragement and his professional assistance and supervision were felt by virtually every student of hydraulic engineering at the University.

In 1929, he made tests by means of models to determine the benefits of proposed cut-offs of the Des Moines River, at Ottumwa, Iowa. This study was probably the first attempt in the United States to determine in advance of actual field construction the benefits to be derived from straightening rivers. Mr. Yarnell was among the first of American engineers to recognize the value of river-model studies which have since been accepted as a necessary part of virtually every major hydraulic engineering project in America.

The J. James R. Croes Medal of the Society was conferred jointly upon Mr. Yarnell and the late Floyd A. Nagler, M. Am. Soc. C. E., of the State University of Iowa, for a paper entitled " The Effect of Turbulence Upon the Registration of Current Meters." [4]

Other significant laboratory investigations conducted by Mr. Yarnell from 1928 to 1933 included the flow of water around bends in pipes of rectangular and circular cross-section, the back-water caused by pile trestles and bridge piers, and the hydraulics of flow over railway and highway embankments. The last of these studies was conducted on models and on full-scale highway and railway embankments tested in the river flume under conditions simulating those found in Nature.

Mr. Yarnell was the author of a *Bulletin* on rainfall frequency-intensity data, in which he made an analysis of 28 077 rain storms representing the combined records of every Weather Bureau Station equipped with automatic rain-gages in the continental United States from its earliest record to the end of 1933. He showed exceptional patience in his analysis of this staggering tangle of statistical data, and presented the material in such form that it is now widely used.[5]

---

[2] " The Flow of Water in Drain Tile," by D. L. Yarnell and Sherman M. Woodward, M. Am. Soc. C. E., *Bulletin No. 854*, U. S. Dept. of Agriculture, Govt. Printing Office (1920).

[3] " Flow of Water Through Culverts," by David L. Yarnell, Floyd A. Nagler, and Sherman M. Woodward, Members, Am. Soc. C. E., *Bulletin No. 1*, Univ. of Iowa Studies in Eng. (June, 1926).

[4] *Transactions*, Am. Soc. C. E., Vol. 95 (1931), pp. 766–795.

More than twenty-five papers and *Bulletins* are directly credited to Mr. Yarnell's authorship. Countless others bear acknowledgments to him for his kindly interest and assistance. To his co-workers and to young men entering upon the study of engineering he gave most generously of his wealth of knowledge and professional experience. His support of the Iowa Hydraulics Laboratory during its early years was a large factor in its rapid development, and his use of graduate students as assistants was extremely beneficial to scores of young men in enabling them to continue their studies while gaining practical experience in hydraulic engineering.

A sensitive man, courteous, mild-mannered, and retiring, "Dave" Yarnell was genuinely loved by those who came to know him well, and he was held in high esteem by all those who made his acquaintance. He exemplified the gentleman whom Julius Hare visioned nearly a century ago when he wrote:

> "The real gentleman should be gentle in everything, at least in everything that depends on himself—carriage, temper, constructions, aims, desires. He ought therefore to be mild, calm, quiet, even, temperate—not hasty in judgment, not exorbitant in ambition, not overbearing, not proud, not rapacious, nor oppressive; for these things are contrary to gentleness."

Mr. Yarnell was a member of the American Society of Agricultural Engineers; the American Geophysical Union; the Iowa Engineering Society; the Engineers Club of Iowa City; the Triangle Club of the University of Iowa; Tau Beta Pi (Honorary Engineering Fraternity); Sigma Xi (Honorary Scientific Society) and other professional and scientific organizations. He was a Mason and a member of the Congregational Church.

On August 24, 1914, Mr. Yarnell was married to Alice Lee Roche, of Washington, D. C. He is survived by his widow, two sisters, Mrs. W. P. Bair and Mrs. Henry Weber; and two brothers, Admiral Harry E. Yarnell, U. S. Navy, and Ross Yarnell Shearon.

Mr. Yarnell was elected a Junior of the American Society of Civil Engineers on April 5, 1910; an Associate Member on October 1, 1912; and a Member on April 21, 1920.

CHARLES ROLLIN ALLEN, Assoc. M. Am. Soc. C. E.[1]

DIED SEPTEMBER 29, 1937

Charles Rollin Allen was born on November 9, 1872, in Williamstown, Vt., the son of C. Rollin and Evelina (Bigelow) Allen. He attended the local schools and also Goddard Seminary, in Barre, Vt. His engineering training was acquired at Tufts College, in Medford, Mass., from which he was graduated in 1899, with the degree of Civil Engineer.

---

[5] "Rainfall Intensity-Frequency Data," by David L. Yarnell, U. S. Dept. of Agriculture, *Miscellaneous Publication No. 204* (1935).

[1] Memoir prepared by C. Rollin Allen, Jr., Saratoga Springs, N. Y.

After his graduation Mr. Allen was first employed as Engineer for the Metropolitan Sewer District, of Boston, Mass., and then returned to Barre as City Engineer. In this position he supervised the installation of the granite block pavement on Main Street, which is still in use. In 1907 he accepted a position with the Highway Department of the State of New York as County Assistant and Location Engineer until 1914, when he set up his own office as Consulting Engineer on highway work.

As a Consulting Engineer for the contractors, he was connected with highway work from Vermont to Buffalo, N. Y., and from Canada to Pennsylvania. This work included many of the noted highways in New York State among which were Storm King, Whiteface, Crow's Nest, and, most recently, the Rensselaer Bridge over the New York Central and Boston and Albany Railroads. He did a great deal of work in the Court of Claims of the State as expert witness on highways, valuation of work done, and uncompleted contracts.

During the World War, Mr. Allen was employed by the Federal Government, first at Nitro, W. Va., and then in the shipyard at Hog Island, Philadelphia, Pa.

As a Consulting Engineer he had a good opportunity to show his infallible patience and good humor, dealing with contractors and representatives of the State, smoothing out their differences, and keeping his work running smoothly to a satisfactory conclusion.

He was married on October 29, 1904, to Mabel S. Calef, who survives him, together with three sons, Stanley C., C. Rollin, Jr., and Richard S., and one daughter, Lucy E. Allen.

Mr. Allen was elected an Associate Member of the American Society of Civil Engineers on June 6, 1911.

RUSSELL AVERILL ANDERSON, Assoc. M. Am. Soc. C. E.[1]

Died May 31, 1937

Russell Averill Anderson was born at Wrightsville Beach, N. C., on August 31, 1896, the son of Burdis Anderson and Ella (Butters) Anderson. He first attended school at Wilmington, N. C., but later his parents moved to Michigan where his mother's family was prominent in the lumbering industry of that State.

Mr. Anderson's parents settled in Sault Ste. Marie, Mich., and there he lived and received his public and High School training until 1914, when he entered Northwestern University, at Evanston, Ill. After three years of academic study, he left the University to join the United States Army Air Corps in which he attained the rank of Lieutenant.

---

[1] Memoir prepared by James H. Cissel, and G. Donald Kennedy, Members, Am. Soc. C. E., and Frederick C. Taylor, M. Am. Soc. C. E.

When the close of the World War ended his military service, he began his technical education in the Engineering College of the University of Michigan, at Ann Arbor, Mich. During the entire period of his studies at Michigan, his class-room training was strengthened and given practical point by part-time employment in the offices of W. C. Hoad and Arthur J. Decker, Members, Am. Soc. C. E., Consulting Engineers, in Ann Arbor.

In 1920, an opportunity, both to gain engineering experience in a wider field and to earn money needed for the completion of his engineering course, resulted in an interruption of his college work. For nearly two years, Mr. Anderson was employed on appraisal work, first by Henry Earle Riggs, M. Am. Soc. C. E., in the United States and, later, by the J. G. White Company, in the Philippine Islands, in an appraisal of the properties of the Manila Light and Power Company.

Returning to the University of Michigan in the spring of 1922, Mr. Anderson was graduated with honors in Civil Engineering with the Class of that year, thus closing a scholastic career in which "he was rated very highly by his teachers, and showed a capacity for getting things done and for doing the job well."

During his college years, his work for Hoad and Decker had included a variety of problems both in the office and in the field. The firm's business was largely concerned with sewerage and water systems and other municipal work, and it was to this field that Mr. Anderson returned when he resumed his connection with the same office after his graduation.

From June, 1922, until October, 1923, he was engaged in preliminary studies, reports, and designs. Comprehensive plans for sewerage were developed by him for the cities of Muskegon, Royal Oak, Trenton, and Owosso, in Michigan. He planned extensive water-works improvements for several other cities in Michigan. From October, 1923, until February, 1924, he managed his firm's Branch Office at Jackson, Mich., where he had charge of the collection of field data pertinent to comprehensive sewerage and drainage plans for that city.

From February to September, 1924, Mr. Anderson made field surveys and office studies, and prepared a report on the disposal of industrial wastes from the automobile plants at Flint, Mich. His work for the next year was concerned principally with sewerage and sewage disposal problems for Oakland County, Michigan, and the City of Adrian, Mich.

Mr. Anderson left the consulting engineering field in October, 1925, and became associated with the R. D. Baker Construction Company, of Royal Oak, Mich. His first work with this Company was in connection with estimating, for bidding purposes, the cost of the Royal Oak Drain, an Oakland County project for the construction of a sewer approximately six miles long and ranging in diameter from 15 ft at the outlet to 6 ft at the upper end. The contract for this project, which was let at a later date, was awarded the R. D. Baker Construction Company for approximately $1 000 000. During

1926, Mr. Anderson was actively engaged in the supervision of the construction of this project.

From the time of his employment by the Baker Company to the middle of 1933, Mr. Anderson, as Vice-President and Secretary, was active in the management of the Company and in the prosecution of several other large projects in Michigan, namely, the construction of 1.5 miles of sea wall along the shores of Lake St. Clair in Grosse Pointe Shores; the construction of several miles of steel water main ranging in size from 72 in. to 30 in. in diameter in Royal Oak, Detroit, and Monroe; a complete water main system for the Village of Inkster, comprising 60 miles of mains; numerous projects and extensions on the Flint sewer system; and many other construction projects of similar nature, including a 16-ft storm sewer consisting of both tunnel and open-cut construction in Dallas, Tex.

In 1933, Mr. Anderson went with the Michigan State Highway Department as Resident Engineer on the project for widening Woodward Avenue, in Detroit. Soon after the completion of this important construction he joined the Administrative Staff of the Department as Director of its Finance Division. In that position Mr. Anderson assumed and admirably discharged the responsibilities connected with the financial, contractual, and procurement operations of the Department in a period not only of great construction activity, but of extreme fiscal uncertainty and confusion. During the four years that he filled this position, the practice of the Department, in relation to construction contracts, accounting, and purchasing was readjusted and practically re-organized under his direction.

So effectively did Mr. Anderson perform the duties of this position that he was counted among the most able administrators in the public service of the State, and, at the time of his death, was being considered for posts of still higher responsibility and trust. The following resolution adopted concurrently by both Chambers of the State Legislature of Michigan reflects the esteem in which he was held:

> "*Whereas,* Russell A. Anderson, finance director of the State Highway Department, died suddenly May 31 in the prime of his life; and
>
> "*Whereas,* He was an able leader in the engineering profession who had given distinguished service to the State Highway Department and to the state of Michigan; and
>
> "*Whereas,* Russell A. Anderson combined rare ability with a keen sense of humor, a pleasing personality and rugged integrity that always revealed him as a fine gentleman; and
>
> "*Whereas,* His untimely death has been a tremendous shock to his colleagues and his many friends who will never forget his beautiful character; now therefore be it
>
> "*Resolved by the House of Representatives* (The Senate concurring), That the members of the Michigan legislature express their profound sorrow on the death of Russell A. Anderson, Finance Director of the State Highway Department; and be it further
>
> "*Resolved,* That copies of this resolution be sent to the widow and to the State Highway Department.
>
> "Adopted June 4, 1937."

As an Engineer and as an Executive, Mr. Anderson exemplified the technical accuracy, the insistent energy, and the integrity of principle and practice which the profession demands. In his personal relations, the same keen intelligence and inherent loyalty which brought promise and fulfillment to his career as an Engineer, made him a friend whose genial companionship and genuine qualities were valued and are remembered by all who knew him.

Mr. Anderson was a Charter Member of the Engineering Society of Detroit, Treasurer of the Michigan Engineering Society, and President of the Michigan Good Roads Federation. In addition, he guided the activities of the Michigan Bureau for Highway Education.

He was married to Marian Van Valen, of Parma, Mich., in 1921, while he was still a student at the University of Michigan. Mrs. Anderson and two children, Suzanne and Russell, survive him.

Mr. Anderson was elected a Junior of the American Society of Civil Engineers on November 26, 1923, and an Associate Member on June 7, 1926.

ALBERT WORTHINGTON ATWATER, Assoc. M. Am. Soc. C. E.[1]

DIED SEPTEMBER 24, 1937

Albert Worthington Atwater, the oldest son of John A. and Clara (Worthington) Atwater, was born in Brooklyn, N. Y., on December 23, 1885. He was of early American stock.

He received his preparatory education in the Public Schools of Springfield, Mass. Entering the School of Mechanical Engineering of Purdue University, at Lafayette, Ind., in 1902, he earned the degree of Bachelor of Science in 1906. Subsequently (1909), he was awarded the professional degree of Mechanical Engineer on the presentation of a thesis on "The Design of the Hulett Patent Movable Car Dumper."

Early in his professional career, Mr. Atwater identified himself with the design of heavy mechanical equipment and, although he became active in other and varied fields of engineering, he never lost interest in this type of work. As a Designing Engineer and, later, as Sales Engineer, he kept in close touch with this important branch of engineering.

He began his professional work with the firm of Wellman-Seaver-Morgan Company, of Cleveland, Ohio, as an Apprentice Draftsman, shortly after graduation from High School. This firm was one of the leaders in the development of mechanical equipment for handling heavy freight, particularly in the rapid loading and unloading of Lake carriers. Mr. Atwater was connected with this Company for eight years,—during college vacations and for four years after his graduation. His work was principally in connection with the design of ore-unloading equipment and coal-loading equipment for boats engaged in Great Lakes transportation. He had much to do with the details of the development of the Hulett movable car dumper.

---

[1] Memoir prepared by a Committee of the Tennessee Valley Section, consisting of Ned H. Sayford, M. Am. Soc. C. E., and J. G. Allen and F. C. Wardwell, Assoc. Members, Am. Soc. C. E.

In 1910, he resigned to accept an appointment as a teacher of Mechanical Drawing in East Technical High School, at Cleveland. He remained in this position for two years.

Mr. Atwater became Chief Draftsman for the Cleveland Illuminating Company in 1912, and, later, was promoted to the position of Construction Engineer in charge of all plant construction and maintenance. As such, he was in complete charge of the design, purchase of equipment, and construction of all steam projects of this Company, including complete plants of a generating capacity as high as 50 000 kw. At this time, he became interested in the Prime Movers Committee of the National Electric Light Association and for several years took an active part in its work. During the time that he was with the Illuminating Company, Mr. Atwater had much to do with the evaluation of physical property in connection with the Company's celebrated rate case with the State of Ohio.

For a short time between 1919 and 1921, Mr. Atwater was employed by Arthur G. McKee and Company on blast-furnace design, but in March, 1921, he again entered the service of the Cleveland Board of Education, this time as Electrical Engineer. The City of Cleveland was undergoing a very rapid expansion in its school-building program. During a period of two years, he supervised the design and construction of the electrical installation on a $15 000 000 school-building program.

In 1923, Mr. Atwater became connected with the E. W. Clark Engineering Corporation which was designing and constructing many large steam-power projects. As the Company's Mechanical Engineer, he was in charge of the first high-temperature, high-pressure electric steam plant. Later, he was in charge of the erection of the 40 000-kw steam plant of the Nashville Railway and Light Company (later, the Tennessee Electric Power Company), at Hales Bar, near Chattanooga, Tenn. In 1925, this plant was referred to as one of the three outstanding steam plants of the United States.

Upon the completion of the Hales Bar Steam Plant, Mr. Atwater became a partner in the contracting firm of Martin and Warlick Company. This firm contracted for and built many schools, factories, motion picture theaters, and garages, in Chattanooga and other cities of Tennessee. At this time he was a member of the Associated General Contractors of America and was President of the Chattanooga Chapter of the Association, and a Director of its State Branch.

In 1927, Mr. Atwater became Mechanical Engineer on the design of steam-power projects for Stone and Webster Engineering Corporation, of Boston, Mass.

Returning to Chattanooga in 1928, he re-entered contracting work and also engaged in sales engineering, acting as the East Tennessee Sales Representative for the Tennessee Products Corporation and several large equipment manufacturers. He also served in an advisory capacity to Street

Brothers Machine Company, in the design of cableways and other heavy construction equipment.

Upon the advent of the Tennesee Valley Authority (TVA), in Tennessee, Mr. Atwater entered the employ of the Authority as an Examining Engineer in the Personnel Division, where he interviewed and was instrumental in hiring a large percentage of the construction personnel for Norris Dam.

Later, he transferred first to the Design Division and then to the Construction Plant Division of the TVA, assisting in the design of construction plants for Chickamauga, Hiwassee, and Guntersville Dams.

With the start of construction of the Chickamauga Project, Mr. Atwater was transferred to that project as Assistant and afterward became Associate Mechanical Engineer. He was later promoted to the position of Progress Engineer, which he held at the time of his death.

In addition to a keen interest in his profession, Mr. Atwater found time to devote much study to history, particularly to the military history of his country. He was an authority on the subject of military operations in the Civil War and, frequently, was called upon to describe the battle formations in the district around Chattanooga, where several decisive battles were fought. His extensive collection of maps and books on the subject is of considerable interest to historians. At the time of his death, he was preparing a series of talks on Civil War movements to be given to the Army Officers studying the tactics and strategy of actions around Chattanooga.

Mr. Atwater was a man of quiet manner, extremely modest, conscientious, and of highest integrity. His dry wit made him an extremely interesting conversationalist.

He is survived by his widow, Ida (Grove) Atwater, to whom he was married at Cleveland, in 1906; also by one son, Grove Worthington Atwater.

He was a member of the Theta Xi Fraternity, a member of the Chattanooga Engineers Club, and was a licensed Professional Engineer in the State of Tennessee.

Mr. Atwater was elected an Associate Member of the American Society of Civil Engineers on September 9, 1919.

JOSEPH DUNTON BROWN, Assoc. M. Am. Soc. C. E.[1]

DIED MARCH 8, 1937

Joseph Dunton Brown, the oldest son of John Dunton and Josephine (Marshall) Brown, was born in Chelsea, Mass., on March 5, 1884. His ancestors were of the earlier settlers of New England. His father, born in Wiscasset, Me., was left an orphan at the age of ten years, his parents being lost at sea while making a voyage to Australia in the *Emily Dunton*. In Boston, Mass., John Dunton Brown met Josephine Marshall, and was married to her in January, 1881. He then moved to Chelsea where, as stated, Joseph Dunton Brown was born.

---

[1] Memoir prepared by J. S. Lewis, Esq., Waterbury, Conn.

Mr. Brown's early life was spent in Chelsea and Everett, Mass., where he attended Grammar and High School. At the age of nineteen he secured a position with the John Hancock Insurance Company. While with this Company, he attended night classes at Lowell Institute, Lowell, Mass., where he studied Civil Engineering. Upon completing his course at the Lowell Institute he accepted a position as Engineer with The Connecticut Company, New Haven, Conn., under Charles Rufus Harte, M. Am. Soc. C. E.

From 1913 to 1918, Mr. Brown was an Engineer with the Connecticut State Highway Department. In 1918, he went to Stevenson, Conn., with the J. A. P. Crisfield Company, working directly under Mr. Crisfield on the construction of the Stevenson Dam for The Connecticut Light and Power Company. On the completion of this project, he went with the Lockwood Greene Company, of Boston, but was with this Company only for a short time, when he was recalled by The Connecticut Light and Power Company and made Real Estate Engineer. Under his superintendence most of the Company's transmission lines were laid out and rights of way surveyed, and purchased. He had a great deal to do with the successful completion of The Rocky River Development which includes the formation of Lake Candlewood, the largest lake in the State.

He was a great lover of his father's native State—Maine—his greatest pleasure being to fish her streams with congenial companions, a pleasure he was able to enjoy several times each year. It was always his wish that he could spend his old age in Maine and, at the time of his death, he was negotiating the purchase of an estate on the Maine Coast.

Mr. Brown was a member of the Board of Fire Commissioners and the Board of Water Commissioners of the Town of Southington, Conn., and a member of the Congregational Church, in New Milford, Conn. He was a member of the Connecticut Society of Civil Engineers. His Masonic affiliations included membership in the Blue Lodge, in Rockville, Conn., Knight Templars, in Danbury, Conn., and the Mystic Shrine, in Bridgeport, Conn.

In 1912, he was married to Gertrude E. Martin, of Rockville, Conn. From this union there are three children, Donald Marshall, Marjorie Janet, and Dorothy Gertrude, who, with Mrs. Brown, survive him. Donald is a graduate of the University of Maine; Marjorie, an undergraduate at the Connecticut College for Women, in New London; and Dorothy, a High School student, thus bearing out Mr. Brown's determination to give his children an easier start in life than he had.

He loved his home in Marion, Conn., and spent much of his spare time beautifying its surroundings, his hobby being forestry and wood-working. He was friendly and affable and took pleasure in doing favors for his friends. It is difficult to replace a man of Mr. Brown's character and attainments; his going is an irreparable loss to both his friends and The Connecticut Light and Power Company.

Mr. Brown was elected an Associate Member of the American Society of Civil Engineers on January 14, 1929.

VERNE LOUIS CONRAD, Assoc. M. Am. Soc. C. E.[1]

Died November 24, 1937

Verne Louis Conrad was born on January 6, 1879, in Bellaire, Ohio, the son of W. Harry Conrad and Elizabeth (Rinker) Conrad. His parents moved to Uhrichsville, Ohio, when he was four years of age, and here he grew up and attended school. It was in the local High School that he became acquainted with his future wife. He attended Ohio State University, at Columbus, Ohio, from which he was graduated in 1902 with the degree of Civil Engineer.

Immediately after leaving college, Mr. Conrad accepted a position with the Engineering Corps of the Pennsylvania Railroad Company, on the Logansport Division, where he was employed in the Maintenance-of-Way Office (June to October, 1902). He was then placed in charge of double-track construction from Logansport, Ind., to Chicago, Ill. (October, 1902, to November, 1903); after which he was transferred to the Cincinnati Division (November, 1903, to August, 1904). From August, 1904, to February, 1905, he was engaged on the design of bridges and grade separation, on the Logansport Division; and from February 1905, to October, 1907, he was in charge of construction for the elimination of Bulger Tunnel and 4-track change alignment, on the Pittsburgh (Pa.) Division.

Mr. Conrad was Superintendent for Butler Brothers Hoff Company, on the Detroit River Tunnel from October, 1907, to March, 1908, and Division Engineer for the Detroit River Tunnel Company, in charge of the Subaqueous Division, until January, 1910.

At that time, Mr. Conrad moved to Texas, locating near Donna, where he was engaged as Engineer on Surveys and Design for the Hidalgo County Drainage District for about one year. He then became Engineer for the Union Irrigation District, at Raymondville, Tex., and was engaged on irrigation work at San Saba, Tex., until November, 1913, when he moved to Cameron County, locating in Brownsville, Tex. His first major engagement in Brownsville was the resurvey of the County boundaries and topographical features, and the preparation of an Official Map of Cameron County, still (1938) in current use. This work required nearly three years.

From March, 1916, until his death, Mr. Conrad was engaged in extensive private engineering practice in Cameron and neighboring counties, with offices in Brownsville. He served as Special Highway Engineer for Cameron County from July, 1919, to January, 1920, and was Engineer for a large number of irrigation districts in Cameron County, among which were the La Feria Irrigation District and Cameron County Water Districts Nos. 8, 10, 11, 16, and 17. He made surveys for the relocation of the Point Isabel Railroad and right-of-way surveys for the Brownsville Navigation District. He also had charge of numerous other surveys, plants, and developments in his locality to the time of his death.

---

[1] Memoir prepared by W. O. Washington, M. Am. Soc. C. E.

Mr. Conrad took an active interest in civic affairs. His keen sense of humor and genial personality made him a friend of all. He was a hard worker, but was always willing to help others.

At Uhrichsville, on October 6, 1904, he was married to Mary Ellen Parry, and theirs was a happy family throughout the years. Surviving him are his widow; his mother, Mrs. Elizabeth Conrad; a son, Verne Louis Conrad, Jr.; and a daughter, Sarita (Mrs. F. C. Whitmer).

Mr. Conrad was elected an Associate Member of the American Society of Civil Engineers on December 6, 1920.

ROSS ELROY HAMILTON, Assoc. M. Am. Soc. C. E.[1]

Died July 24, 1937

Ross Elroy Hamilton, the son of James and Jane (Leggett) Hamilton, was born in Coshocton County, Ohio, on September 1, 1879. He received his early education in the country schools of the County, taking his High School work at Coschocton High School from which he was graduated in June, 1899. In September of the same year he entered the Ohio State University, at Columbus, Ohio, from which he was graduated in 1903 with the degree of Civil Engineer.

Mr. Hamilton's engineering experience began in May, 1903, as Transitman with the Pennsylvania Railway Company. He continued in railroad work until 1908, being employed, successively, by the New York Central and Hudson River Railway Company on grade reduction work; as Assistant City Engineer with the City of Urbana, Ill.; as Instrumentman by the New York Central and Southwestern Railroad Companies; as Assistant Engineer, Department of Maintenance and Way, Baltimore and Ohio Railway Company; as Instrumentman on location and construction, Tidewater Railroad Company; and as Engineer in charge of masonry structures on line reconstruction work, by the Southern Railway Company, at Lynchburg, Va.

In February, 1908, Mr. Hamilton returned to Coshocton and entered the private practice of his profession. He supervised the field work on a 6-mile dam, acted as City Engineer, and designed and supervised the construction of the disposal plant, water-works, and storm-sewer system for West Lafayette, Ohio.

In September, 1909, he took office as County Engineer of Coshocton County, serving two terms of two years each. He then served two years as Division Engineer in the Department of Public Works, in charge of the Ohio and Erie Canal, and one year as Assistant Division Engineer in the Department of Highways, at New Philadelphia, Ohio. He was then re-elected as County Engineer of Coshocton County and served two terms. He resigned this office in 1920 to accept a position with the State Highway Department as Resident Engineer of Coshocton County. He continued as Resident Engineer until 1934 when he resigned to re-enter private practice, being employed by the City of Coshocton as Supervising Engineer in charge of the new water-works construction. He served a period with the Muskingum Conservancy District, at New Philadelphia, and returned home in 1936, resuming private work. He had several municipal projects under way when he became ill.

---

[1] Memoir prepared by S. S. Senter, Esq., Canton, Ohio.

Mr. Hamilton was interested and active in civic life and its problems, wherever he was located. He was a life-long member of the Democratic party and took an active part in its councils. The confidence of the community in his ability and integrity was expressed in his election as County Engineer on four different occasions.

He was a member of the Masonic Fraternity, a Kiwanian, and an active member of the Presbyterian Church, serving frequently in various official capacities.

He stood high in his profession and had the respect of his professional associates and of all those who knew him. There was something about his appearance and conversation that gave the impression of honesty, which was his outstanding characteristic. He was fair and " square " in all his dealings and the profession has lost a man who followed in his work and every-day life, its highest ideals.

In his many years of service to the community of Coshocton County, Mr. Hamilton has left numerous monuments to his memory. He is sometimes spoken of as the " father " of the Coshocton County System of Highways because through his efforts there are many miles of highly improved roads which will be a reminder of his service for many years to come.

In his private life he was a splendid family man, a good companion, kindly, sincere, and honorable. He made and kept friends because of his genuine worth and stability, his lack of pretence, and his unconquerable spirit. His passing is a distinct loss to the profession and to the community, and his many friends and the surviving members of his family will miss him sorely.

He was married at Coshocton, on June 16, 1909, to Adeline Merrill and in his home life he was very fortunate and supremely happy. His widow and one son, Thomas, survive him. For them it may be said, " Love hath a tie which Time nor Death can sever."

Mr. Hamilton was elected an Associate Member of the American Society of Civil Engineers on April 1, 1914.

FOSTER WARREN HARVEY, Assoc. M. Am. Soc. C. E.[1]

DIED JUNE 11, 1937

Foster Warren Harvey was born in Nashua, Iowa, on September 5, 1899. He was educated in the public schools of Sioux Falls, S. Dak., and later attended the University of South Dakota, at Vermilion, from which he was graduated as an Honor Student, with the degree of Bachelor of Science in Civil Engineering, in the Class of 1923.

---

[1] Memoir prepared by Ray Adams, Assoc. M. Am. Soc. C. E.

Immediately after his graduation, Mr. Harvey accepted employment with the Illinois State Division of Highways. After serving approximately two months as an Instrumentman and Inspector, he was appointed Resident Engineer on earth grading, bridges, and paving. In July 1925, he entered the service of Carr and McFadden, Consulting Engineers, of Palm Beach, Fla., as Chief of Party on development work for subdivisions and Designer of reinforced concrete and steel structures. The major part of his field work was in the swampy districts of Florida. He found the sub-tropical climate and conditions to be quite unsuited to him, and, therefore, he again sought employment in a more temperate locality. In October, 1925, he was engaged as a Designer by the firm of Harrington, Howard, and Ash, Consulting Engineers, of Kansas City, Mo. His duties with this firm consisted of design of details, and preparation of design drawings for fixed and movable bridges, the most notable of which was the railroad truss of the Mississippi River Bridge, at Vicksburg, Miss.

In March, 1928, he was employed by the Bureau of Bridges, Missouri State Highway Commission, as a Designer, and remained in this position until his death. Mr. Harvey's period of employment with this Bureau coincided with the largest program of highway bridge construction in the history of the State. He was engaged almost entirely in responsible charge of preliminary investigations, design, and the supervision of the preparation of design plans for bridges of major proportions, across navigable streams. The most notable of these is the highway bridge across the Missouri River on U. S. Route 40 TR, at Weldon Springs, Mo. This is a 32-ft roadway bridge of 2 614 ft over-all length. The river spans are two 2-span continuous trusses with a span of 513 ft, center to center of piers. This bridge was dedicated and formally opened on June 26, 1937.

Mr. Harvey was a member of the Protestant Episcopal Church, and a member of the Vestry of Grace Episcopal Church, in Jefferson City, Mo. He was active in lay affairs of his Church. In Masonic circles, he was a member of the Blue Lodge in Jefferson City. He was a member of the Independent Order of Odd Fellows.

Mr. Harvey served in the Army, in a training camp, during the latter part of 1918. Upon graduating from the University of South Dakota, he was appointed a Second Lieutenant in the Officers Reserve Corps, U. S. Army. He was later promoted to the grade of First Lieutenant, and, in August, 1933, to that of Captain, Infantry Reserve. He received a Certificate of Capacity for the grade of Major, Infantry Reserve, in May, 1937, and would have been promoted to that grade upon the occurrence of the first vacancy after August, 1938. He was a member of the Reserve Officers Association and participated in its activities.

He was stricken with meningitis on June 6, 1937, and succumbed to this illness on June 11, at his home in Jefferson City. Funeral services were held in Grace Episcopal Church in Jefferson City, and he was buried with military honors at Sioux Falls, S. Dak. He is survived by his mother, Mrs. Myrtle L. Harvey, with whom he had made his home for the past thirteen years.

In all his work, Mr. Harvey was outstanding for his thoroughness and ingenuity. He was singularly vigorous in his attack of difficult problems, and completed his solution with the same degree of energy that he displayed at the beginning. He often expressed his belief that the excellence of a bridge design depended largely upon the ingenuity and thoroughness exercised in the design of details. He was considered the leading authority in the Missouri Highway Department on the design of steel bridges. He was very patient with those of his professional associates whose experience did not equal his, and always proved himself willing to be of assistance to them. His associates feel that his death interrupted a career that was just beginning to ripen to its full potentiality.

Mr. Harvey was elected an Associate Member of the American Society of Civil Engineers on November 28, 1931.

CLARENCE SCOTT HOWELL, Assoc. M. Am. Soc. C. E.[1]

Died September 23, 1936

Clarence Scott Howell, the son of William Roe Howell and Fanny (Scott) Howell, was born in New York, N. Y., on August 11, 1875. He was in direct descent from Edward Howell, founder of Southampton, N. Y., and Captain Nathaniel Roe of the Continental Army. His father was a noted artist and photographer, receiving among other awards the American Institute Medal for the best full-length pastel in 1873, and the Great Medal of Merit from the Vienna Exposition in the same year.

As a boy, influenced by his father's vocation, Clarence Scott Howell showed proficiency in photography and studied art in New York City and Brooklyn schools. These studies were interrupted by the death of the father, and the boy had to seek remunerative employment. He was appointed a page in the United States House of Representatives during President Cleveland's Second Administration. In Washington, D. C., Mr. Howell continued his studies at Columbian College, the Corcoran Art School, and the Art Students' League.

In 1895, he received an appointment as Photographer in the Washington, D. C., Navy Yard, and, in 1896, he was transferred to the Engineering Department at the Norfolk (Va.) Navy Yard, where he remained until he resigned as Assistant Engineer, in 1906. It was at this time that he decided to make engineering and architecture his life work.

---

[1] Memoir prepared by Herbert W. Ferris, Assoc. M. Am. Soc. C. E.

In 1907, Mr. Howell as Superintendent for the Raymond Concrete Pile Company, built the foundations for the Contagious Disease Hospital and the Baggage and Dormitory Buildings, at Ellis Island, New York Harbor.

From 1908 to 1916, in private consulting practice, with offices in Washington and New York City, as a member of the firm of Howell and Howell, Engineers and Architects, and as the Chief Engineer of the Giant Concrete Pile Company, Mr. Howell specialized in the design of heavy foundations, the more notable being: The substructure for the all-concrete ocean pier, at Long Beach, N. Y.; the foundation and superstructure for the reinforced concrete bridge and approaches across Reynolds Channel, also at Long Beach; and the foundation and superstructure for an elastic arch bridge spanning Popolon Creek and Valley, New York. At the request of Major J. M. Carson, U. S. Army, he was consulted on the design of the foundations for the West Academy Building of the United States Military Academy, at West Point, N. Y.

During this period Mr. Howell made a special study of concrete piles, and of pile-driving methods and apparatus. These studies resulted in his designing the "Giant Concrete Pile", a reinforced concrete pile driven from the point. This method of pile-driving was patented by Mr. Howell in the United States Patent Office (Patents No. 1,352,128, September 7, 1920, and No. 1,366,460, January 25, 1921). These piles were used in the foundations of the following buildings: Power House, Manhattan State Hospital, on Ward's Island, New York, 1916; United States Court House, Custom House and Appraisers Stores, at Wilmington, N. C., 1916; and Factory No. 4, Mutual Chemical Company of America, at Baltimore, Md., 1920.

In 1916 the Giant Concrete Pile Company became affiliated with the North-Eastern Construction Company of New York City. Mr. Howell became associated with the latter Company as Designing and Field Engineer until the re-organization of the Giant Concrete Pile Company in May, 1920. He became Vice-President and Chief Engineer in this new Company and also re-established himself in private practice in New York City, until 1930.

In addition to his achievements in heavy foundation work, Mr. Howell designed and supervised the construction of many types of structures, namely, reinforced concrete garages and industrial buildings, office buildings, piers, sea-walls, and private residences.

In 1930, he again became associated with the North-Eastern Construction Company, in New York City, as Designing and Field Engineer, which position he held at the time of his death.

On May 9, 1918, Mr. Howell was commissioned Captain, Engineers, United States Army. He commanded Company B, 551st Engineer Service Battalion, at Camp A. A. Humphreys, Virginia. His orders for duty overseas were cancelled at the time of the Armistice and he was honorably discharged from the Army, on January 10, 1919.

He was an indefatigable worker, yet he found time to contribute articles to engineering magazines, photography, painting, and collecting rare tropical plants. Mrs. Howell has presented his plant collection to the New York

Botanical Gardens, where it is exhibited as a memorial to him. Conspicuous among his contributions to engineering literature are the following: In *Engineering News:* "Straight or Tapered Piles", February 25, 1912; and in *Engineering News-Record:* "A New Concrete Pile", March 2, 1916; "Validity of Pile Formula", April 27, 1916; and "Bottom Driven Concrete Piles on Government Job", December 28, 1916. An article entitled "Concrete Pile Standards" was published in *Concrete,* in July, 1917.

At the time of his death Mr. Howell was engaged in writing the memoirs of his days as a page in the House of Representatives, and a novel, the locale of which was the Great Smokies of Tennessee. These works he left unfinished.

Taking an active part in civic and community affairs, he gave freely of his time and engineering knowledge toward the betterment of his community. He was held in high esteem by his fellow townsmen for he was a man of sterling character and quiet habits, and his judgment was solicited on all important movements.

On January 1, 1896, at Washington, D. C., he was married to Nannie G. Cook, daughter of General George W. Cook, veteran of the Civil and Indian Wars. He is survived by Mrs. Howell, two daughters, Mrs. Frederick R. Hawley and Mrs. Richard Carroll; three grandchildren, Nancy Carroll, Richard Carroll, Jr., and Virginia Hawley; and a brother, Frank Scott Howell.

He was licensed as a Professional Engineer of the State of New York on January 27, 1918.

Mr. Howell was elected an Associate Member of the American Society of Civil Engineers on November 27, 1917.

JACOB DUNCAN JAQUES, Assoc. M. Am. Soc. C. E.[1]

DIED SEPTEMBER 10, 1936

Jacob Duncan Jaques was born in Woodbury, N. J., on November 15, 1878, the son of Edwin Thomas and Charlotte Louise (Duncan) Jaques. From his parents he received an heritage of family tradition reaching back to early Colonial times. His first formal instruction was obtained in two schools rich in historic associations, the Friends Select School and the William Penn Charter School, in Philadelphia, Pa. To attend these schools he journeyed back and forth daily from Woodbury over the trains and ferries then in use, not foreseeing that he would have a part in providing the faster transportation of the present. At the age of 19 he entered the University of Pennsylvania to study Civil Engineering and was graduated in 1901 with the degree of Bachelor of Science in Civil Engineering.

---

[1] Memoir prepared by a Committee of the Philadelphia Section, consisting of C. E. Myers and Charles H. Stevens, Members, Am. Soc. C. E., and Charles A. Howland, Assoc. M. Am. Soc. C. E.

Immediately after his graduation, Mr. Jaques secured a position as Transitman on the construction of a sewerage system for Woodbury, and, in September, 1901, was given charge of the work. He left Woodbury in January, 1902, to work as Transitman for Ford, Bacon, and Davis, on the construction of a street railway between Ardmore and Llanerch, Pa., but returned, in March, to Woodbury and resumed charge of the sewerage work as Resident Engineer. Leaving Woodbury in October, 1902, he was employed for six and one-half years by the Philadelphia Rapid Transit Company on the construction of the Market Street Subway and Elevated Railway. First, as Transitman in charge of a corps on general field work, he made the surveys, including through levels and base-line measurement for the West Market Street Elevated Line. He was then placed in charge of the location and construction of foundations in the more than three miles of this work and, in December, 1905, he was promoted to the position of Assistant Engineer and given charge of the construction of about a mile of the East Market Street Subway from Eighth Street to the Delaware River.

After the completion of the rapid transit work in March, 1909, Mr. Jaques was engaged by the United States Government as Inspector in charge of building the superstructure of the Cross Ledge Light Station, in Delaware Bay. In March, 1910, he assumed the duties of General Superintendent in charge of construction for Hungerford and Terry, a Philadelphia firm specializing in water-filtration construction. An opportunity came, however, to take charge of construction work in Western Pennsylvania for the Atlantic Refining Company and, in 1911 and 1912, he was engaged upon this work in Braddock and Ridgway, Pa. Returning in 1913 to Eastern Pennsylvania, he entered upon four years of important work for the New Jersey Zinc Company at the Palmerton, Pa., plant. As Assistant Chief of Construction, he was in charge of the Company's forces varying from 100 to 500 men, on plant improvements and additions costing $4 000 000. The principal structures erected included an oxide trestle, 1 200 ft long, of steel superstructure on concrete piers; a lithopone plant comprising frame and steel buildings on concrete foundations; a $1 000 000 addition, 900 ft long, to the existing oxide plant; and an acid plant also costing $1 000 000. This latter was a complete unit for the manufacture of fuming sulfuric acid and included buildings of frame, brick, and steel, overhead piping, machinery installation, sewers, water mains, and railroad trackage. One of the most difficult undertakings was the reconstruction of a blast furnace which necessitated foundation reconstruction of the furnace while in fire, rapid demolition of the old furnace, and erection of the new.

When the United States entered the World War, Mr. Jaques enlisted in the Civil Engineer Corps of the Naval Reserve Force, was commissioned Lieutenant (Senior Grade), and served at the Boston (Mass.) Navy Yard as Assistant to the District Public Works Officer. Placed in charge of construction contracts in the First Naval District, he saw erected under his supervision the Naval Radio School on Cambridge Common; the Naval Training School, on Bumkin Island, in Boston Harbor; additions to the Chelsea

Naval Hospital, at Chelsea, Mass.; additions to the Naval Air Station, at Chatham, Mass.; and a coal-handling plant in South Boston. When, in 1919, he received his discharge from the Federal Service, he returned to Philadelphia and entered the employ of the Department of City Transit where he was assigned to studies of the foundations of existing buildings to determine the underpinning which would be required for the proposed South Broad Street Subway. In 1920, however, he left the City service to take charge of the erection for the Empire Zinc Company of a zinc oxide plant, at Canon City, Colo. This work, costing $1 000 000, included, in addition to the oxide furnace building, a bag house, brick ore kilns, cooperage and fan buildings, and offices.

Returning in 1921 to Eastern Pennsylvania, Mr. Jaques was employed as Engineer by M. and T. E. Farrell, Contractors, on the construction of 5 000 ft of the reinforced concrete Lincoln Highway through Downingtown. Upon the completion of this work, he entered private practice in the contracting field and in the years 1922–1924, contracted for and built sewage disposal plants at West Collingswood, N. J., and Woodlynne, N. J.; a sea wall at National Park, N. J.; and a main pipe tunnel of concrete for the Camden County Tuberculosis Hospital, at Asyla, N. J. In 1925, he returned to the Department of City Transit, in Philadelphia, as Assistant Construction Engineer and was engaged for four years principally upon special investigations and reports for the Chief Engineer. These reports covered a variety of subjects, including paint best suited for concrete surfaces in subway stations, methods for stopping leaks in completed subway under back-fill, type of face brick most suitable for the terminal shop buildings, cost of ventilation wells, payment for installation of new gas mains, study to recommend a plan for handling traffic during subway construction, and an analysis of contractors' claims.

In 1930, he obtained a leave of absence from the Philadelphia Department of City Transit to enter the employ of the Shell Eastern Petroleum Products, Incorporated, upon the construction of bulk terminals. As District Engineer for the Company he had charge of building the terminal at 37th and Reed Streets, Philadelphia, and one in Trenton, N. J. The former construction involved hydrographic surveys followed by dredging in the Schuylkill River, erection of timber bulkhead, grading of plant area, and the installation of storage tanks with piping, pumps, and fire-walls. At Trenton, the work covered principally the installation of tanks with their auxiliary equipment.

In October, 1930, Mr. Jaques returned to the position of Assistant Construction Engineer in the Philadelphia Department of City Transit and was placed in immediate charge of subway and underground concourse construction beneath and east of the City Hall. Because of the tremendous loads to be supported under the continually occupied City Hall and the poor quality of the existing building foundations, the work presented great difficulties. It was necessary to proceed with the utmost care, and constant study and close supervision were required. From this work he went to take charge of constructing 7 200 ft of two-track subway in South Broad Street from Kater Street to Snyder Avenue. This construction included, in addition to the subway trench proper, three stations and their entrances, underpinning of buildings, relocation and restoration of underground structures, and paving of sidewalks and street surface. As the subway structure was situated in the east half of Broad Street and had a sub-grade depth of 30 to 35 ft below street level, it was necessary to underpin nearly all buildings along the eastern house line. Construction difficulties were increased by the large quantities of water encountered along the entire line and by stretches of bad ground which required excavation below plan sub-grade and the use of steel sheet-piling.

In 1933, the construction of a high-speed line was begun across the Delaware River between Philadelphia and Camden, N. J. Mr. Jaques was employed by the Delaware River Joint Commission first on the supervision of work under a $1 000 000 contract for a two-track subway to connect the existing subway in North Eighth Street, Philadelphia, with the west end of the bridge line. Later, he was transferred to the Design Division where he was engaged upon special problems in connection with the relocation of structures owned by public utilities and, in co-operation with the Commissioners of Fairmount Park, upon the restoration of historic Franklin Square.

To undertake the last work upon which he was to be engaged, he returned to the scene of an earlier activity. For the New Jersey Zinc Company, he took charge of engineering and working forces on the rapid construction of a large plant addition at Palmerton, Pa. The underpinning of foundations carrying heavy dead and live loads was an important part of an operation which included building foundations, erection of steel, and the installation of mills, conveyors, and other equipment. The work was carried on day and night in order to meet time requirements for completion. From Palmerton he returned to his home in Philadelphia and was with his family when stricken by the attack of acute appendicitis which, in a few days, caused his death.

Few engineers are privileged to achieve as largely as Mr. Jaques in their chosen field and, at the same time, to make and keep the friendship of so many with whom they come in contact through the years. He was highly regarded for his ability in the field of engineering, particularly in construction, and, to this, the works which his energy and resourcefulness brought to successful completion, testify. More than this, however, his genial personality, enduring friendliness, and keen interest endeared him to many. His circle of friends was broadened by a fondness which he had from early boyhood for trap-shooting. He grew to be an outstanding expert in the sport, and this avocation brought him into organizations of kindred spirits where he did much to develop the art.

He was interested in activities for the benefit of the profession and joined with other engineers in organizations for this purpose but, like others whose work takes them frequently to new locations, he could not always retain these memberships. He was a Registered Professional Engineer in Pennsylvania for many years, a member of the Sons of the American Revolution, and also a member of several gun clubs.

On February 8, 1921, he was married, in Oakmont, Pa., to Grace Vernon Hunter who, with his daughter, Louise, survives him.

Mr. Jaques was elected an Associate Member of the American Society of Civil Engineers on November 1, 1910.

WILLIAM EDWARD JOHNSON, Assoc. M. Am. Soc. C. E.[1]

Died June 30, 1937

William Edward Johnson was born at Glastonbury, Conn., on March 10, 1867, the son of Giles M. and Emily (Allen) Johnson. His education was received at Williston Academy, Easthampton, Mass., the Connecticut Literary Institute, Suffield, Conn., and Lehigh University, Bethlehem, Pa.

Shortly after leaving college (1890), Mr. Johnson entered the employ of the Board of Water Commissioners of the City of Hartford, Conn., as Assistant Engineer in charge of reservoirs. In 1895, he was appointed Engineer in charge of the Reservoir Division. This position he held until May 18, 1936, when due to illness, he was retired on pension. During his long period of service, he saw the growth of the Hartford Water Supply System (under the Board of Water Commissioners which, later, was succeeded by the Water Bureau of The Metropolitan District Commission of Hartford County), from several small reservoirs in the immediate vicinity of Hartford, to the present system embodying the Nepaug Reservoir, 15 miles from Hartford, completed in 1918, and the Barkhamsted Reservoir, 25 miles from Hartford, now (1938) nearing completion.

Mr. Johnson was in active charge of construction and surveys for additional water supply in the progressive improvement of the West Hartford Reservoir System. He gave to his work a sincere and absorbing interest which produced that quality of supervision and reliability essential to the proper administration of public service, and like many another, the value of his services was not fully realized until after his passing.

In 1892, Mr. Johnson was married to Florence May Alford. He is survived by three sons, Hubert Edward Johnson, Alfred William Johnson, and Giles Meigs Johnson, and one daughter, F. Ruth Johnson.

He was a member of Wyllys Lodge (Masons), Washington Commandery, Knights Templar, Jeremiah Wadsworth Chapter, Sons of the American Revolution, Connecticut Society of Civil Engineers, the Connecticut Historical Society, and during the World War he served in the Connecticut Home Guards.

---

[1] Memoir prepared by Caleb Mills Saville, M. Am. Soc. C. E.

Mr. Johnson was elected an Associate Member of the American Society of Civil Engineers on April 3, 1901.

CHARLES WILLIAM HENRY NESSLER, Assoc. M. Am. Soc. C. E.[1]

DIED OCTOBER 7, 1937

Charles William Henry Nessler was born in Mountain View, Calif., on December 18, 1890, the son of Charles W. H. and Catherine (Hannon) Nessler.

His formal education ended with the completion of Grammar School in Mountain View and near-by San Francisco. Although Mr. Nessler was denied the opportunity to gain a college education, he acquired a thorough knowledge of topographic engineering by practical experience in the field and constant study at home.

He began his engineering experience as a Rodman and Recorder with a topographic field party of the United States Geological Survey during the summer of 1912 in the San Joaquin Valley of California. The outdoor life so appealed to him that he decided to make every effort to continue with the organization. However, he early recognized that without further education and study his progress would be limited. Lack of funds prevented formal attendance at college, and an intensive course of home study seemed the only solution. Soon, thereafter, he enrolled with the International Correspondence Schools, at Scranton, Pa., in a course of Surveying and Mapping.

During the next few years Mr. Nessler continued with the U. S. Geological Survey in the capacity of Rodman and Recorder, working with various field parties engaged in topographic mapping in the State of California. The winter of 1916–1917 was spent with the Interstate Commerce Commission, as Chainman and Rodman in connection with railroad valuation work.

With the completion of the course in Surveying and Mapping and the experience gained over a period of four or five years, he was prepared to enter the classified Civil Service. On May 14, 1917, Mr. Nessler was appointed a Junior Topographer in the U. S. Geological Survey, and with the exception of his World War service, he continued with this organization until his death.

His first assignment was to make a topographic survey of a part of the Santa Lucia Range on the coast of California. This was followed by geodetic and topographic surveys in various parts of the Pacific Coast States, including Arizona and Idaho. His enthusiasm and energy, combined with a natural aptitude for delineating topographic features, were quickly recognized and as a result he was given some of the more difficult and important assignments.

His work with the U. S. Geological Survey was temporarily interrupted by the World War. He enlisted on March 11, 1918, and served as Private

---

[1] Memoir prepared by Conrad A. Ecklund, M. Am. Soc. C. E.

First Class with Company A, 29th Engineers. One year of his enlistment was spent overseas in France and while there he contracted rheumatic fever which left his heart in a weakened condition. After the Armistice he accompanied the Army of Occupation into Germany, returning to the United States in July, 1919.

On July 18, 1919, Mr. Nessler received his honorable discharge from the Army and two days later was reinstated in the U. S. Geological Survey as an Assistant Topographic Engineer. On July 11, 1924, he was promoted to the position of Associate Topographic Engineer, which title he held at the time of his death. Following his reinstatement with the Survey he again felt the need of further study and accordingly enrolled in special courses with the La Salle Extension University, of Chicago, Ill., and with the University of California, at Berkeley, Calif.

In 1922, when the U. S. Geological Survey entered into a co-operative agreement with the County of Los Angeles to make a topographic map of that County, Mr. Nessler was one of the first engineers to be selected for this very important work; he spent the next three years mapping a considerable part of the southern and more densely populated area. The original plan provided for mapping only the south one-third of the County. This was completed in the fall of 1925. Mr. Nessler was then assigned to river surveys in the State of Oregon, and for the next two years he was engaged in making river and dam-site surveys in the States of Oregon and Arizona, and in the office preparation of the data obtained in the field. In 1928, he had topographic mapping assignments on the Mt. Jefferson Quadrangle, in Oregon, and the Turret Peak Quadrangle, in Arizona.

When work was resumed in 1929 on the Los Angeles County Project, Mr. Nessler was again assigned to this work, remaining until the topographic map of Los Angeles County was completed in the spring of 1937. Then followed his last field assignment, the mapping of a mountainous area in Arizona. The recurrence of the ailment contracted during the World War brought an abrupt termination to his field career. Throughout his entire service he possessed not only marked topographic ability, but also those other qualities, both physical and personal, that are so necessary to the successful planning and execution of field assignments under unusual and often hazardous conditions.

Mr. Nessler was a member of American Society of Photogrammetry, and a member of the Sacramento Section of the Society. He also took an active interest as a member of the American Legion Post No. 127, of Glendale, Calif.

Untiring in work, strong in character, keen in intellect, and possessed of a high sense of personal responsibility for public service, Mr. Nessler leaves his organization and friends greatly indebted to his activities.

He was married on September 19, 1920, to Isabel Barcroft, of Madera, Calif., and is survived by his widow, a daughter, Evelyn M., a son, Harry J., and a brother, S. J. Nessler.

Mr. Nessler was elected an Associate Member of the American Society of Civil Engineers on June 15, 1936.

SVEN ALBERT NORLING, Assoc. M. Am. Soc. C. E.[1]

DIED FEBRUARY 4, 1937

Sven Albert Norling was born in Söderhamm, on the Baltic Coast, in the northern part of Sweden, on March 21, 1894. A true Viking, he was descended on his father's side from a line of sea captains and on that of his mother from a family of artists, of whom his grandfather was a painter of note. He was one of a family of five children.

He attended the public schools and a private High School in Söderhamm. He obtained his first college degree at Ultuna Agricultural and Engineering College, at Upsala, Sweden, in 1917, after which he spent a year studying at Halle an der Saale, an old university town in Germany. Returning to Upsala on a scholarship in the fall of 1918, Mr. Norling received his Master's Degree the following year, majoring in land reclamation engineering. In 1919, he was a Teacher at Molkom High and Agricultural School, in the Province of Värmland. In May, 1920, he accepted a position with the Swedish Royal Water Commission as a Civil Engineer in Charge of Topographic Surveys in connection with regulation works on Lake Vänern and the Trollhättan Hydro-Electric developments.

Mr. Norling was one of ten successful applicants for as many Swedish-American scholarships out of a total of 200 and sailed for the United States in the fall of 1920 for a year's study at the University of Wisconsin, Madison, Wis. While there, he pursued special studies in hydraulic and drainage engineering and after the conclusion of his year's work received an appointment as Research Assistant at the University of Minnesota on investigations on the behavior of ground-water. In the fall of 1923, having finished the curriculum required by the University of Wisconsin, he received the degree of Doctor of Philosophy from that institution. His thesis dealt with the effects of the elevation of the ground-water table on yields of various kinds of crops, a field of research in which very little work had been done in the United States prior to that time.

In 1924, Mr. Norling established a consulting office in Minneapolis, Minn., and until the time of his death had acted in a consulting capacity in many parts of the United States. He was one of the Engineering Consultants on the Great Lakes Water Level Case, in which a number of the Lake States were involved. He was also a member of the Minneapolis Water Supply Commission appointed in 1932 to study ways and means of improving the water pressure in the southern part of the city and removing objectionable tastes and odors from the city supply.

From 1934 to the time of his death, Mr. Norling served, successively, as Consulting Hydraulic Engineer for the Civil Works Administration, State Emergency Relief Administration, and Works Progress Administration on a number of water conservation projects undertaken by the State of Minnesota in co-operation with these agencies.

---

[1] Memoir prepared by a Committee of the Northwestern Section, consisting of E. V Willard and Adolph F. Meyer, Members, Am. Soc. C. E.

While engineering was his chosen field of work, he engaged extensively in farming. The possibilities of peat lands to produce intensively of vegetables and truck-farm products appealed to him, with the result that he always interested himself in peat-land farming. At the time of his death, he was operating a 500-acre truck farm near Forest Lake, Minn., where he employed from forty to fifty men during the summer seasons.

In 1921, Mr. Norling was married to Borgny Kirsten Myhr, herself a graduate of the University of Oslo, at Oslo, Norway, whom he had met before coming to the United States. Besides Mrs. Norling, he is survived in this country by two daughters, Karin and Celia, and one son, Gunnar.

He was a Registered Professional Engineer in Minnesota, a Scottish Rite Mason, and a member of "Svenska Sällskapet," a club made up mostly of Swedish professional men residing in Minneapolis and St. Paul.

Mr. Norling was elected an Associate Member of the American Society of Civil Engineers on June 6, 1927.

BEALE MELANCTHON SCHMUCKER, Assoc. M. Am. Soc. C. E.[1]

DIED DECEMBER 23, 1937

Beale Melancthon Schmucker, whose career closely paralleled the development of automotive highway transportation in the United States, contributed greatly to that development in Southern New Jersey.

Beale Melancthon Schmucker was born on September 22, 1888, the son of Dr. and Mrs. Samuel C. Schmucker. His father is a beloved Professor Emeritus at State Teachers' College, at West Chester, Pa., a well known lecturer on scientific subjects, and an author of note. His mother is also well known in her field, having illustrated a number of her husband's books. With such a background, it is not difficult to understand why Mr. Schmucker considered his position one of public trust, and discharged his duties in accordance with the best engineering principles. He was a graduate of the University of Pennsylvania, at Philadelphia, Pa., in the Class of 1911, with a degree of Bachelor of Science in Civil Engineering.

For several years Mr. Schmucker was County Engineer for the County of Camden, in New Jersey. He came to Camden County, in 1912, after one year in the employ of the City Engineer of Ocean City, N. J. In 1915, he became the Assistant County Engineer and in 1929, the County Engineer.

During the twenty-six years of his service to Camden County, automobile registration in the United States increased from 900 000 to 24 000 000, or more than twenty-six times. New Jersey had more than its proportionate share of this growth. Situated between Philadelphia and Atlantic City, Camden County early received its quota of very heavy traffic. To solve this problem the then County Engineer, the late John J. Albertson, M. Am. Soc. C. E., and his Assistant, Mr. Schmucker, early adopted a durable and safe hard surface concrete, for their new and re-constructed highways. Of this material they constructed the Camden County Section of the famed White Horse Pike, and, later, Mr. Schmucker, as County Engineer, built the Camden County Section of the Black Horse Pike. These highways are known throughout the East and at the time of their construction embodied the most advanced thought in highway design.

---

[1] Memoir prepared by S. Herbert Taylor, Esq., Camden, N. J.

Mr. Schmucker was one of the pioneers in the adoption of the lane idea in highway design. On the Camden County Section of the Black Horse Pike, constructed in 1929, the lanes, in addition to being built into the highway proper, are built into the intersections. This was the first such use of this method in New Jersey.

During the period of the World War, Mr. Schmucker relinquished his County duties to serve with the 104th Engineers, 29th Division. He was swiftly promoted from Private to Captain, being commissioned First Lieutenant in command of his Company in August, 1917, and Captain in March, 1918. As Captain, he took part in both the Argonne and Meuse Offenses.

Besides serving Camden County and his country, Mr. Schmucker served well his fellow engineers. Long an active member of the Society, he also took an interest in the affairs of the Licensed Engineers' Association. He served as President of the South Jersey Chapter and was serving as President of the parent body, the New Jersey Association of Professional Engineers and Land Surveyors, at the time of his death. Many of his engineering associates will long remember his courage, sacrifice, and unfailing devotion to this trust during his long illness. Many a time his wife, Jean Roser Schmucker, drove him 80 or 100 miles to a meeting, and then put him to bed in a hotel room for a few hours, in order that he might gain strength enough to conduct the meeting.

He served as President of the New Jersey Association of County Engineers for one term. He was a member of the Camden Club, the Camden Lodge of the Benevolent and Protective Order of Elks, and the Tavistock Country Club.

Like his distinguished father, he was a lover of the out-of-doors, and all his hobbies—hunting, fishing, and golf—were connected with it. His personality was forcible and direct, happily relieved by a jovial sense of humor.

Mr. Schmucker was elected an Associate Member of the American Society of Civil Engineers on October 9, 1917. He was an active member of the Philadelphia Section, serving on various Committees, and as a Director from 1929 to 1931.

WILLIAM LEE SELMER, Assoc. M. Am. Soc. C. E.[1]

DIED JULY 11, 1937

William Lee Selmer was born in Boston, Mass., on August 29, 1885, the son of William and Hulda (Lee) Selmer. His parents moved to Brooklyn,

---

[1] Memoir prepared by Charles J. Slipper, Asst. Engr., Transit Comm., New York, N. Y.

N. Y., during his early years and he lived in New York, N. Y., and its environs, for the remainder of his life. He received his education in its public schools and at Cooper Union, from which he obtained the degree of Bachelor of Science in 1907, and that of Civil Engineer in 1911.

Probably due to his father's influence, early in life he became interested in topographical surveying and other engineering work and began his career with a city surveyor on title insurance surveys before he was seventeen.

While completing his education, Mr. Selmer earned his living and obtained experience in various engineering positions. After a competitive examination, he entered the service of New York City in 1903 as a Rodman with the Board of Rapid Transit Railroad Commissioners, in which position he was engaged in the construction of the city's first subway.

After a year and a half of this subway work, he spent two and one-half years in the Topographical Bureau of the Borough of Richmond. He was engaged on the mapping of the city plan for that Borough, which work was then at its height. He returned to the Rapid Transit Board just before it was replaced by the Public Service Commission for the First District. This Commission was created by New York State's first Public Utility Regulation Act, and its members assumed office on July 1, 1907. Mr. Selmer spent the remainder of his life in the employ of the State of New York with this Commission and its successors.

Soon after taking office, the members of the Commission directed their attention, under their regulatory powers over steam railroads, to conditions at highway-railroad grade crossings on the trunk railroads in New York City. With a view to separating their grades or improving protection at the crossings, a staff was organized to make engineering analyses of the various situations and problems at the 400 or more such crossings in the city and to report to the Commission, at first under the direction of Daniel L. Turner, M. Am. Soc. C. E. From 1911 to the time of his death, on July 11, 1937, such matters were largely under Mr. Selmer's immediate charge. Although his engineering activities were concerned principally with grade-crossing elimination in New York City, they also covered regulatory work for the Commission in rapid transit operation, maintenance, and inspection of track and structures to insure safety in operation and of passengers. During his time, grade crossings in New York City were reduced in number by more than one-half. More than $35 000 000 was expended, and an elimination program adopted covering the remaining crossings over which high-speed railroad trains operate, which will bring the total cost to more than $50 000 000.

Mr. Selmer's chief interests centered in his family and in his engineering work—to them he was ever faithful, above all else. His predominating characteristics—modesty and sincerity—were immediately recognized by those who had contact with him.

Mr. Turner, in a letter of condolence to the family, said of him:

> "Always he could be depended upon. He had my confidence from the beginning. It was a great pleasure to have him as an associate. His record with the Commission has been outstanding, and a fine example of a most praiseworthy and unselfish service. It will not be forgotten soon."

Robert Ridgway, Past-President, and Hon. M. Am. Soc. C. E., in a similar communication, said:

"Having been associated so long, directly and indirectly, with Mr. Selmer, I feel keenly his loss. A faithful public servant, I wish his work was better known to the public at large. We who knew how ably and conscientiously he worked and how he gave his best to his duties, will miss him."

On his death the Transit Commission caused to be spread upon its Minutes the following resolution which admirably epitomizes the man, his career, and the feelings of those who knew him:

"It is with painful feelings that the Commission notes on its records the death of William L. Selmer, which, on July 11, 1937, brought to an untimely close his faithful and fruitful public service of thirty years, during which he fulfilled to the utmost every duty laid upon him, and they were many. As engineer in charge of grade crossing eliminations he brought to the varied and difficult problems involved in securing public safety an ability, professional skill, resourcefulness, tact, and unlimited devotion to duty which left nothing to be desired. All over the great City of New York various structures of earth, steel and concrete stand today as enduring monuments to his useful and efficient life.

"To his host of friends the poignancy of grief is sharpened by remembrance of those lovable human qualities which he possessed to an unusual degree and which made him in every sense a complete man liked and respected of men.

"To his surviving wife and family, the Commission extends its deepest sympathy in their great sorrow for the loss of a faithful and loving husband and father who leaves after him as a source of solemn pride the fruits of work well done, an unblemished record and a spotless character."

On April 28, 1914, he was married to Emily Josephine Whaley, who, with two daughters, Olive and Joan, are left to mourn his passing.

Mr. Selmer was elected a Junior of the American Society of Civil Engineers on March 31, 1908, and an Associate Member on March 2, 1915. He was also a member of the Municipal Engineers of the City of New York.

PHILIP SCOTT TYRE, Assoc. M. Am. Soc. C. E.[1]

DIED AUGUST 25, 1937

Philip Scott Tyre was born in Wilmington, Del., on July 14, 1881. He was the oldest of three children of James and Eliza (Bow) Tyre, whose families were early settlers in the State of Delaware.

At the age of six, young Philip entered the Wilmington Public Schools, and, in 1899, he was graduated with honors from the Wilmington High School. During this time he helped meet the family budget by working Saturdays and selling newspapers on the streets of Wilmington. During his High School days he took a special course in draftsmanship, and upon graduation he entered the employ of the Edge Moor Bridge Works, as a Draftsman.

---

[1] Memoir prepared by Reynold H. Greenberg, Esq., Philadelphia, Pa.

In 1900, Mr. Tyre associated himself with the New York Shipbuilding Company as an Engineer. In 1903, in order that he might study art, he accepted a position with the Patterson Contracting Company, of Denver, Colo., and attended night classes in the Denver School of Art. Mr. Tyre returned to the New York Shipbuilding Company in 1904. In 1907 he was made Chief Engineer of the Belmont Iron Works, of Philadelphia, Pa. Once again, Mr. Tyre furthered his art studies by attending the Pennsylvania Academy of The Fine Arts in Philadelphia, and after his graduation he was awarded a Fellowship in the Academy.

In 1908, he became associated with George F. Pawling and Company, acting, successively, as Structural Draftsman, Chief Draftsman, and, later, as Chief Engineer of the Company. In this position he had responsible charge of designing office, mill, mercantile, and factory buildings, as well as tank towers, bridges, etc.

In 1914, he left the Pawling Company to enter private practice as an Architect and Engineer, but when the United States entered the World War, because of his experience, particularly in marine engineering, Mr. Tyre was called to the Emergency Fleet Corporation. In the spring of 1918, he was appointed Progress Engineer in charge of all Districts of the Corporation; and, later, he became Assistant Head of the Inspection and Production Department, Division of Ship Construction. In 1919, he was made Assistant to the Vice-President, Mr. J. L. Ackerson, in complete charge of ship construction. During his engagement with the Emergency Fleet Corporation he organized, systematized, and invented master records of ship construction for the entire Emergency Fleet Corporation. He inaugurated and planned the Fourth of July Launching Program of the Emergency Fleet Corporation in 1918, under which one hundred ships were launched in one day, a feat never before attempted. In 1920, Mr. Tyre was honorably discharged from the Emergency Fleet Corporation and resumed his private practice as an Architect and Engineer. He maintained his offices in the Architects Building, in Philadelphia, until his death.

The story of Philip Scott Tyre's life should really be written in two chapters, because when, in February, 1929, he lost the use of his right arm through paralysis, with an indomitable will seldom seen in any man, he refused to give up his activities in engineering and architecture; and, further, he refused to give up the hobby that he loved so dearly—painting. He learned to use his left hand, and one of the greatest tributes ever paid to any man was when the Art Club of Philadelphia announced a One-Man Exhibit in 1935 of the works of Philip Scott Tyre. All the paintings on exhibition had been completed after his affliction.

Mr. Tyre was particularly active in the design and construction of automobile buildings, and to-day, in Philadelphia, there are scores of such buildings that remain as monuments to his originality and architectural genius. Among the many structures he designed in Philadelphia were buildings for the Packard Motor Company, Cadillac Motor Company, Nash Motor Company, Hupmobile Company, Graham-Paige, and many others. Upon the completion of the Nash Building, in Philadelphia, Mr. C. W. Nash, President of the Nash Motor Company, publicly stated that in all his automobile experience, he had never visited any automobile sales and service building that was quite as complete in detail as the Nash Philadelphia Building. Mr. Tyre was an Honorary Member of the Philadelphia Automobile Trade Association, and all the National Automobile Shows held in Philadelphia, were designed and operated under his direction.

As an Architect and Engineer, Philip Scott Tyre never followed, but always led. He was the first man in Philadelphia to construct a large building utilizing concrete for all exterior facades, and he received nation-wide commendation for his handling of the Lasher Printing Company Building, in which the front facade was treated architecturally in poured concrete.

In 1907, he was married to Mabel C. Marcy, of Philadelphia, who survives him, as do his three daughters—Jean Campbell (Mrs. Gerry Mason), who was the Assistant Dean of Skidmore College; Marjorie Cole (Mrs. Robert McGinnis), harpist with the Philadelphia Symphony Orchestra; and Sarah Marcy, a teacher at the Episcopal Academy, in Philadelphia.

At his death Mr. Tyre was a member of the Philadelphia Section of the Society; a member of the American Institute of Architects, Philadelphia Chapter; Associate Member of the American Society of Naval Architects and Marine Engineers; Art Club of Philadelphia; a Fellow of the Pennsylvania Academy of The Fine Arts; member of the Engineers Club of Philadelphia; American Federation of Art; Pennsylvania Museum; and School of Industrial Art. He was also a member of the Union League and North Hills Country Club, in which he was a Director and Chairman of the Building Committee.

In recent years, Mr. Tyre enjoyed nothing more than to go to his country home in Erwinna, Bucks County, Pa., where he did most of his painting and reading. He was particularly proud of his fine library of engineering and architectural editions. He was also a prolific worker in oil; and it was while sketching at Erwinna that he became ill. On August 25, 1937, the Philadelphia daily papers, as well as the Associated Press, carried the news of his death to his friends and associates all over the United States. So ended a beautiful life that, while not full when measured by years, was truly full when measured by achievement.

Mr. Tyre was elected an Associate Member of the American Society of Civil Engineers on July 9, 1912.

HENRY RADCLYFFE ST. ARVANS WALTERS, Assoc. M. Am. Soc. C. E.[1]

Died February 23, 1937

Henry Radclyffe St. Arvans Walters was born at Ashby, Suffolk County, England, on October 24, 1875, the son of the Rev. Edmond Walters and Anne

---

[1] Memoir prepared by W. A. Hazard, Assoc. M. Am. Soc. C. E.

Elizabeth (Browne) Walters. He received his early education at King's School, Warwick, England.

In 1892, when Mr. Walters was seventeen years of age, his father brought the family to the United States and located in California. In March, 1896, Mr. Walters entered the employ of the Llewellyn Iron Works at Los Angeles, Calif., as Special Apprentice, where he remained for two years, or until March, 1898, when he entered the shops of the Santa Fé, Prescott and Phoenix Railway Company, at Prescott, Ariz., remaining there until August, 1899.

In the fall of 1899, Mr. Walters came East and entered Lehigh University, at Bethlehem, Pa., from which he was graduated in 1903 with the degree of Civil Engineer. During his college years, he was employed in the summer vacation periods, as follows: In 1900 in the Ordnance Shops of the Bethlehem Steel Company, at Bethlehem; in 1901 he was employed in the Easton, Pa., Shops of the Lehigh Valley Railroad Company; and, in 1902, he was in charge of the assembly and erection of structural steelwork for the Guerber Engineering Company, of Bethlehem, which work included the erection of a 360-ft cantilever single-track railroad span at Beavers Run, Pa.

After his graduation from college, Mr. Walters again became associated with the Guerber Engineering Company in successive capacities of Chief Draftsman, Chief Engineer, and Superintendent of Manufacture. He remained with this firm until 1908, when he entered the employ of the Bethlehem Steel Company, as Superintendent of the Fabricating Shops, Saucon Division, of the Bethlehem Plant. In this capacity, he served for about two years, and, in 1910, was placed in executive charge of the Fabrication Department as Engineer of Fabrication, which position he occupied until 1916.

For the succeeding years, covering the period of the World War, Mr. Walters' duties were of a very special and often of a very confidential nature. He was given charge of construction, except plant construction, which included principally the development of housing projects, and was thus engaged until 1922. At the time of the consolidation of the Cambria Steel Company and the Lackawanna Steel Company with the Bethlehem Steel Company, Mr. Walters was assigned the duty of co-ordinating the Operating Departments of the three Companies, and, finally, re-organizing the Fabricating and Structural Sales Departments into the Fabrication and Erection Department, of which he became Manager, and in which capacity he continued until 1931.

On January 1, 1931, the McClintic-Marshall Company, of Pittsburgh, Pa., was consolidated with the Bethlehem Steel Company, and Mr. Walters became Assistant to the President of the McClintic-Marshall Corporation, which position he occupied until 1936, when this Corporation was dissolved. From that time until his death, he was a member of the General Sales Department of the Bethlehem Steel Company in a consulting capacity, and with special assignments in connection with the development of sales activities.

Through his long association with the Bethlehem Steel Company and his intimate connection with its development, Mr. Walters' services were of inestimable value, and his advice and opinions were constantly being sought in the development and enlargement of the Company's facilities. He enjoyed a wide circle of friends and acquaintances, and was recognized as a man of sterling qualities, fair in all his dealings with his fellow men, an able executive, and a true friend to all his associates.

Mr. Walters is survived by his widow, Dorothy Griffin Walters, four sisters and four brothers.

He was a member of Minsi Lodge No. 733 F. and A. M., and Ezra Chapter No. 201, Royal Arch Masons, Red Cross of Constantine, Mary Conclave No. 5. He was also a member of Trinity Episcopal Church, of Bethlehem, Pa.

He was a past member of the Board of Governors of the Bethlehem Chamber of Commerce, a member of the Bethlehem Club, Northampton Country Club, and Lehigh Valley Engineers' Club.

Mr. Walters was elected a Junior of the American Society of Civil Engineers on October 6, 1903, and an Associate Member on April 5, 1905.

WARREN WITHEE, Assoc. M. Am. Soc. C. E.[1]

Died February 3, 1938

Warren Withee was born at Minneapolis, Minn., on April 4, 1893, the son of H. W. Withee and Harriett (Brewer) Withee. After finishing his studies in the local grade schools, he attended the University of Minnesota from which he received the degree of Bachelor of Science in Engineering in 1915.

After graduation from the University, Mr. Withee took the position of Assistant Engineer with George A. Ralph, Consulting Engineer, of St. Paul, Minn., acting as Chief of Party and Office Engineer on surveying and office computations for drainage ditches, etc. He held this position from June, 1915, until October, 1917, when he entered the United States Army and served, successively, as Private, Corporal, and Sergeant in the 29th and 74th Engineers, in France. His work consisted of locating enemy artillery by sound ranging, surveying base lines, and locating positions.

Upon his return to the United States in March, 1919, Mr. Withee became Chief of Party for the City of St. Paul on measuring and cross-sectioning streets for paving assessments. From October, 1919, to April, 1920, he acted as Chief of Party in preliminary surveys for drainage ditches for S. B. Gardner, Consulting Engineer, of Benson, Minn. During 1920, he served for a time as Valuation Engineer for the Chicago, Burlington, and Quincy Railroad Company.

From November 18, 1920, until his death, Mr. Withee was Principal Assistant to the District Engineer in the Water Resources Branch of the United States Geological Survey, at Chattanooga, Tenn., entering this service as Assistant Engineer and progressing to the grade of Hydraulic Engineer.

---

[1] Memoir prepared by C. E. McCashin, M. Am. Soc. C. E.

Mr. Withee assisted in all the water resources investigations in co-operation with the U. S. Army Engineers, during the period when the Tennessee River survey was made and continued in this work with the advent of the Tennessee Valley Authority in the construction of projects for the development of the Tennessee Valley. He assisted also in compiling water resources data in the Cumberland Valley and in the Mississippi Valley, in Western Tennessee.

For several years Mr. Withee was a member of the Chattanooga Engineers' Club, the Tennessee Valley Section of the Society, and the American Geophysical Union.

On August 9, 1922, he was married to Nelle Dorsey, of Chattanooga, who survives him.

He had a charming personality which made his friends legion. He was an able hydraulic engineer and an excellent executive. He was a gentleman, a friend, a soldier, and an untiring worker whose place both personally and officially will be difficult to fill. His genial disposition, his kindly assistance and loyalty to all his friends and associates will always be a cherished memory to those who knew him.

Mr. Withee was elected an Associate Member of the American Society of Civil Engineers on September 9, 1935.

WALTER McILHANEY WOLFE, Assoc. M. Am. Soc. C. E.[1]

DIED MAY 11, 1937

Walter McIlhaney Wolfe was born on December 4, 1887, at Chatham, N. J., the son of William James Wolfe, M.D., and Clara (McIlhaney) Wolfe. Dr. Wolfe was a distinguished man who, by choice, through the years had maintained an unique position as minister to the bodily ailments, as well as the spiritual and economic problems, of his neighbors and friends in his section of New Jersey, without thought for his own gain.

Walter McIlhaney Wolfe's ancestors were equally distinguished, having come to Pennsylvania from Alsace in 1751, taking a prominent place in the government and the upbuilding of that and of the neighboring sections—one, George Wolfe, having served as Governor of Pennsylvania from 1829 to 1835.

After preparation in local schools, Walter Wolfe was matriculated on September 5, 1904, at the Virginia Military Institute, at Lexington, Va. During each year of his 4-yr course at the Institute, he stood among the first ten in his class in scholarship. He was graduated on June 24, 1908, with the degree of Bachelor of Science in Civil Engineering ranking third among the candidates for this degree.

After graduation, he entered the employ of the North-Eastern Construction Company, of New York, N. Y., serving as Inspector of concrete pile foundations for the seventeen Isolation Wards of the United States Immigrant Station, at Ellis Island, New York Harbor, and as Office Engineer in connection with the construction of the buildings proper.

---

[1] Memoir prepared by Mason Garber, M. Am. Soc. C. E.

In August, 1909, Mr. Wolfe was appointed Assistant Engineer for the Gore-Meenan Company, in connection with the construction of the Garrison Tunnel, of the Catskill Aqueduct, later becoming Engineer for C. M. Bolton and Company on the Millwood Tunnel and Open Cut, and the Putman Siphon of the Catskill Aqueduct, of the water supply for New York City.

After a term as Assistant Engineer and Superintendent, with the Litchfield Construction Company on heavy construction work, in November, 1912, he became associated with Frederick L. Cranford, Incorporated, on the construction of part of the Dual Subway System for the City of New York, including Church Street Subway, Vesey Street Tunnel, Beekman Street Tunnel, Park Place Station, and crossings under existing Broadway and Park Row subways. His work in collaboration with the late James C. Meem, M. Am. Soc. C. E., of the Cranford Company, served as a model for later subway construction methods.

In 1914, Mr. Wolfe was granted the degree of Civil Engineer by the Virginia Military Institute.

On May 8, 1917, he resigned from the Cranford Company and entered service with the 15th Company (Engineers) at Plattsburgh Barracks, N. Y., and on May 16 was commissioned Captain of Engineers, United States Reserve. Assigned to 6th U. S. Engineers, Captain Wolfe was appointed Battalion Adjutant at Camp Belvoir, Virginia, in July, 1917, and in September, he was made Regimental Adjutant, later serving as Post Adjutant, at Washington Barracks, Washington, D. C. On December 4, 1917, he sailed with his regiment on board the U. S. S. *George Washington*. With the 6th Engineers he participated in the Somme Defensive (5th Army, British Expeditionary Force); in the defense of Amiens, with the Australian Corps (4th Army, B. E. F.); and with the Third Division of the American Expeditionary Force, in the actions of the Champagne-Marne and the Aisne-Marne during July, 1918.

He was returned to the United States in September, 1918, with a cadre of the Third Division, A. E. F., to train a new Sapper Regiment. This same month he was promoted to be Major of Engineers, U. S. Army, with rank from July 30, 1918.

After assignments with the Training Section, Office of Chief of Engineers, in Washington, and as Assistant Professor of Military Science and Tactics (Engineers) at the Massachusetts Institute of Technology, in Cambridge, Mass., he was discharged, at his own request, at the Office of the Chief of Engineers, Washington, D. C., on August 4, 1919.

In 1923, Major Wolfe was commissioned Lieutenant Colonel, Engineers Reserve, and from 1931 to 1935, served as Colonel of the 376th Reserve Regiment of Engineers. From 1935, until his retirement in December, 1936, he served as Commanding Officer of the 375th Reserve Regiment of Engineers.

On his release from active service with the Army, he again became associated with the North-Eastern Construction Company, directing its construction operations at the Aberdeen Proving Grounds and the Edgewood Arsenal, in Maryland. He was later put in complete charge of that Company's operations in Delaware, Maryland, and the District of Columbia, and maintained his District Office, in Baltimore. In 1924, he was elected a Vice-President of the Company and remained active in that capacity until his death, which occurred suddenly from a heart attack on May 11, 1937, at the University Club, in Baltimore. He was buried in Arlington National Cemetery.

During his eighteen years of service as District Manager and Resident Vice-President with the North-Eastern Construction Company, a great number of large and creditably executed construction projects were completed under his immediate direction and supervision. Among the more important were the McComas Street Terminal for the Western Maryland Railroad; the Nurses Home for the Baltimore City Hospital; the Guilford Pumping Station for the Bureau of Water Supply, City of Baltimore; a building group for the Franciscan Novitiate, at Folly Quarter, Md.; the Federal Land Bank, at Baltimore; the Reptile House for the National Zoological Park in Washington, D. C.; a filtration plant for Hagerstown, Md.; and a great many other building and engineering projects in that vicinity.

Colonel Wolfe was at all times active in the affairs of his profession, serving as a Director of the Baltimore Building Congress and Exchange, as well as Secretary of the Baltimore Builders' Chapter of the Associated General Contractors of America.

He maintained his active interest in his military connections, serving as Vice-President of the Third Corps Area of the Society of the Third Division, was a Past Commander of the Military Order of Foreign Wars, Maryland Commanders, a member of the Military Order of the World War, the German H. H. Emory Post of the American Legion, the Society of American Military Engineers, and the Sojourners.

He also held membership in the University Club, of Baltimore; the Torch Club; Scottish Rite, A. F. and A. M., and the Mystic Shrine; the Junior Order of United American Mechanics, of Madison, N. J.; the Rotary Club, of Baltimore; a member of the Executive Committee, Virginia Military Institute Alumni Association, and a Past-President of the Baltimore Chapter.

The recognition accorded Colonel Wolfe's efforts in his chosen vocation, his military service, and his civic activities, best indicate the measure of the man.

In 1914, he was married to Mary Douglas MacNaughtan, daughter of the Rev. Dr. John MacNaughtan, of Chatham, N. J., and is survived by his widow, a daughter, Margaret Douglas Wolfe, and a son, Walter McIlhaney Wolfe, Jr., a sister, Katharine M. Wolfe, and one brother, William C. Wolfe.

Colonel Wolfe was elected an Associate Member of the American Society of Civil Engineers on November 25, 1919.

EDWIN BRIGHTMAN, Jun. Am. Soc. C. E.[1]

Died October 6, 1937

Edwin Brightman, the son of Charles L. Brightman and Charlotte (Clarkson) Brightman, was born at Holyoke, Mass., on October 23, 1911. His father was elected a member of the Faculty of Syracuse University, at Syracuse, N. Y., in 1916, and the children received their early education in the Syracuse Public Schools.

Mr. Brightman was graduated from Nottingham High School in 1929, and entered the College of Applied Science, at Syracuse University, in September of that year. He was enrolled in the course in Civil Engineering and was graduated from that Division with the degree of Bachelor of Science in Civil Engineering in June, 1933. He made an excellent scholastic record in his college course. He was a member of Tau Beta Pi, Theta Tau, and Sigma Phi Epsilon Fraternities, and was active in other matters pertaining to student affairs. His friendship was enjoyed by his classmates and Faculty associates.

Although he completed his college course during the industrial depression, Mr. Brightman immediately found employment, and was engaged for about two years on part-time engineering projects, including geodetic surveying for the Civil Works Administration in up-State New York, a drainage survey for the Smith Canastota Company, at Canastota, N. Y., and design work for the Paper and Pulp Department of the New York State College of Forestry at Syracuse. On March 1, 1935, he secured a position with the Guardian Life Insurance Company of New York, N. Y., as Inspector and Appraiser, which position he was holding at the time of his death.

Mr. Brightman was married to Carol Marion, of Stamford, Conn., on April 7, 1937. He died on October 7, 1937, at his home in Brooklyn, N. Y., after a short illness due to typhoid fever. He is survived by his widow, his parents, and two sisters.

His untimely death cut short a career of unusual promise, and he will be missed by a host of friends who loved and admired him.

Mr. Brightman was elected a Junior of the American Society of Civil Engineers on October 30, 1933.

JAMES DANIEL MICKEY, Jun. Am. Soc. C. E.[2]

Died July 6, 1937

James Daniel Mickey was born in Lincoln, Nebr., on May 15, 1913, the son of Clark Edwin and Irene (Eddy) Mickey. He received his education in the public schools of his native city from which he was graduated in 1931. He then entered the College of Engineering of the University of Nebraska, at Lincoln, from which he received the degree of Bachelor of Science in Civil Engineering, in June, 1935.

---

[1] Memoir prepared by a Committee of the Syracuse Section, consisting of Louis Mitchell and Edward F. Berry, Members, Am. Soc. C. E.

[2] Memoir prepared by Clark E. Mickey, M. Am. Soc. C. E.

While attending High School, he became interested in preparing for an engineering career. During the vacation periods, he was employed by the Abel Construction Company on highway construction and by the Lancaster County Engineer's Office on survey parties.

During the period of his college education Mr. Mickey was employed part time by his father, Clark E. Mickey, M. Am. Soc. C. E., as Rodman, Draftsman, and Computer. During the summer of 1934 he was engaged in the Maintenance-of-Way Department of the Chicago, Burlington and Quincy Railroad Company, in Lincoln, as Rodman, Draftsman, and Computer on construction and maintenance surveys.

After his graduation from the University of Nebraska, Mr. Mickey was employed from June to November, 1935, in the Engineering Division of the Chicago, Burlington and Quincy Railroad Company as Rodman, Levelman, and Computer, during the reconstruction of railway lines which had been destroyed by a major flood of the Republican River in Colorado and Nebraska. When this work was completed, he was engaged from November, 1935, to January, 1937, by the Central Nebraska Public Power and Irrigation District, of Hastings, Nebr., as Levelman, Instrumentman, Detailer, Designer, and Assistant Office Engineer during the surveys, design, and preliminary construction of irrigation canals, structures, and a large earth dam. During the following month, he served as Instrumentman and Party Chief with the Loup River Public Power District, of Columbus, Nebr., on surveys for the location of high-tension electric power transmission lines. He severed his connection with the District in order to accept a more permanent position in the Engineering Department of the Phillips Petroleum Company, at Bartlesville, Okla. While engaged in this work, he was stricken with a virulent attack of poliomyelitis and passed away in the Menorah Hospital, in Kansas City, Mo. He was buried beside his twin sister, Justine R. Mickey, in the family plot in Wyuka Cemetery, in Lincoln.

Mr. Mickey's sudden and untimely death was a severe shock to his family, friends, and associates. He is survived by his father and mother and two sisters, Janice E. Mickey and Jeannette C. Mickey.

While attending the University of Nebraska, Mr. Mickey was a member of the Freshman football squad, Reserve Officers Training Corps, Pershing Rifle Company (Military), Nebraska State National Guard, Scabbard and Blade, and the Student Chapter of the American Society of Civil Engineers. He maintained a high scholarship and was an earnest and excellent student. Much of his time and ability was devoted to his many friends, associates, and college activities. His manner was straightforward, but he was kindly, courteous, and thoughtful toward others.

Throughout his brief career as an Engineer, he was appreciated and respected by his many friends and engineering associates and received many commendations from his employers and superiors. His character, personality, demeanor, and actions won him the confidence and trust of those with whom he was associated. He was a member of the Westminster Presbyterian Church of Lincoln.

Mr. Mickey was elected a Junior of the American Society of Civil Engineers on August 17, 1936.

LAWRENCE KING SNYDER, Jun. Am. Soc. C. E.[1]

DIED NOVEMBER 14, 1937

Lawrence King Snyder was born in Linn Creek, Mo., on October 5, 1906. He received his early education in the local schools and at Fayette High School, at Fayette, Mo. Later he attended Central College, at Fayette, and the Missouri School of Mines and Metallurgy, at Rolla, Mo., from which he was graduated in 1929 with the degree of Bachelor of Science in Civil Engineering.

Mr. Snyder had worked as Rodman and as Concrete Paving Plant Inspector, at Sikeston, Mo., for the Missouri State Highway Department during summer months previous to his graduation. Following graduation, he began work in his chosen profession as Bridge Designer, having served in that capacity, successively, for the Cleveland, Cincinnati, Chicago, and St. Louis Railway Company, at Cincinnati, Ohio, the Missouri State Highway Department, at Sikeston, and the St. Louis-San Francisco Railway Company, at St. Louis, Mo., continuing in the latter position until 1931, when he engaged in private engineering practice, making surveys and preparing plans and estimates for county highway bridges in Missouri.

Mr. Snyder returned to the Missouri School of Mines and Metallurgy in September, 1931, for graduate study in Structural Engineering. He prepared his thesis on the use of "Influence Lines in Calculation of Bridge Stresses," and received the degree of Master of Science in Civil Engineering in 1932. He was elected to membership in the Honor Society of Phi Kappa Phi, and the Engineering Society of Theta Tau.

He then was employed by the Missouri State Highway Department in the Bridge Department, at Jefferson City, Mo., during the years 1933 and 1934, and up to April, 1935, when he was re-employed by the St. Louis-San Francisco Railway Company as Bridge Designer, with headquarters at Springfield, Mo. Mr. Snyder continued in this position, working principally on the design of grade separation structures, until his health failed in June, 1937.

He was a very popular young man, of pleasing personality, and his many friends will regret his untimely passing. He was a member of the Sigma Nu Fraternity. He was not married. His nearest surviving relative is his grandmother, Mrs. L. S. Snyder, of Eldom, Mo.

Mr. Snyder was elected a Junior of the American Society of Civil Engineers on February 23, 1932.

---

Titles of papers are in quotation marks when given with the author's name.

VOLUME 103

SUBJECT INDEX

ADDRESSES.

Presidential Address at the Annual Convention at Salt Lake City, Utah, July 20, 1938. Henry Earle Riggs. 1647.

AGRICULTURE.

"Reclamation as an Aid to Industrial and Agricultural Balance." Ernest P. Goodrich and Calvin V. Davis. (With Discussion.) 181.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

"The Relation of the National Society to the Engineering Profession": Address at the Annual Convention, Salt Lake City, Utah, July 20, 1938. Henry Earle Riggs. 1647.

BACK-WATER.

"Back-Water and Drop-Down Curves for Uniform Channels." Nagaho Mononobe. (With Discussion.) 950.

BEAMS.

"Pre-Stressed Reinforced Concrete and Its Possibilities for Bridge Construction" Ivan A. Rosov. (With Discussion.) 1334.

BIBLIOGRAPHY.

A list of books and publications on surveying. 801.
Flow characteristics in elbow draft-tubes. 434.
References on soil reactions in relation to foundations on piles. 1215.
References on soil stabilization. 1181.

BRIDGE FLOORS.

"Economics of Highway-Bridge Floorings of Various Unit Weights." J. A. L. Waddell. 515. Discussion: Jonathan Jones, Henry C. Tammen, Miller McClintock, Joseph G. Shryock, C. Calor Mota, W. G. Fowler, and Philip A. Franklin. 537.

BRIDGES.

"Interaction Between Rib and Superstructure in Concrete Arch Bridges." Nathan M. Newmark. 62. Discussion: A. Floris, Frank M. Baron, A. A. Eremin, and Hardy Cross. 81.

"Pre-Stressed Reinforced Concrete and Its Possibilities for Bridge Construction." Ivan A. Rosov. (With Discussion.) 1334.

BUTTRESSES.

"Stresses Around Circular Holes in Dams and Buttresses." I. K. Silverman. (With Discussion.) 133.

CEMENT.

Admixtures of Portland cement and bituminous materials in the stabilization of soils. 1171.

CHANNELS.

See **WATER, FLOW OF, IN OPEN CHANNELS.**

COSTS OF WORK.

"Economics of Highway-Bridge Floorings of Various Unit Weights." J. A. L. Waddell. (With Discussion.) 515.

"Economics of the Ohio River Improvement." C. L. Hall. (With Discussion.) 1527.

"Water Transportation Versus Rail Transportation": A Symposium. Rufus W. Putnam, and S. L. Wonson. (With Discussion.) 1279.

DAMS.

"Construction and Testing of Hydraulic Models, Muskingum Water-Shed Project." George E. Barnes and J. G. Jobes. (With Discussion.) 227.

"Hydraulic Tests on the Spillway of the Madden Dam." Richard R. Randolph, Jr. (With Discussion.) 1080.

"Selection of Materials for Rolled-Fill Earth Dams." Charles H. Lee. 1. Discussion: T. T. Knappen, Paul Baumann, William C. Hill, A. Floris, Fred D. Pyle, Joel B. Cox, Stanley M. Dore, John E. Field, William P. Creager, Joseph Jacobs, C. H. Kadie, Jr., Ralph Bennett, R. R. Proctor, and L. F. Harza. 19.

"Stresses Around Circular Holes in Dams and Buttresses." I. K. Silverman. 133. Discussion: R. D. Mindlin, Chesley J. Posey, J. H. A. Brahtz, V. L. Fedorov, F. W. Hanna, C. P. Vetter, and Fred L. Plummer. 149.

See, also, **WATER, FLOW OF, OVER DAMS AND WEIRS.**

DIKES.

Quabbin Dike built by hydraulic fill method. 1396.

DOWEL-BARS.

"Effect of Dowel-Bar Misalignment Across Concrete Pavement Joints." Arthur R. Smith and Sanford W. Benham. (With Discussion.) 1133.

DRAFT-TUBES.

"Flow Characteristics in Elbow Draft-Tubes." C. A. Mockmore. (With Discussion.) 402.

EARTH PRESSURES.

"Graphical Distribution of Vertical Pressure Beneath Foundations." Donald M. Burmister. (With Discussion.) 303.

"Pressures Beneath a Spread Foundation." D. P. Krynine. 827. Discussion: O. K. Fröhlich, Donald W. Taylor, Jacob Feld, G. P. Tschebotareff, A. Hrennikoff, Robert G. Hennes, T. A. Middlebrooks, A. A. Eremin, M. M. Buisson, and Frederick J. Converse. 850.

EARTHQUAKES.

"Earthquake Resistance of Elevated Water-Tanks." Arthur C. Ruge. (With Discussion.) 889.

EARTHWORK.

"Selection of Materials for Rolled-Fill Earth Dams." Charles H. Lee. (With Discussion.) 1.

ECONOMICS.

"Economics of Highway-Bridge Floorings of Various Unit Weights." J. A. L. Waddell. (With Discussion.) 515.

"Economics of the Ohio River Improvement." C. L. Hall. (With Discussion.) 1527.

The economic aspects of flood control. 570.

ENGINEERS AND ENGINEERING.

"The Relation of the National Society to the Engineering Profession": Address at the Annual Convention, Salt Lake City, Utah, July 20, 1938. Henry Earle Riggs. 1647.

EXPANSION (HEAT).

"A New Theory of Rail Expansion." Alfred Africano. (With Discussion.) 465.

FERTILIZERS.

Data on sale of sludge for fertilizer. 1709.

FINANCE.

"Economics of the Ohio River Improvement." C. L. Hall. (With Discussion.) 1527.

FLOODS.

Abstract of Flood Control Act, approved June 22, 1936. 662.

"National Aspects of Flood Control": A Symposium. James J. Davis, Abel Wolman, Nathan B. Jacobs, W. F. Uhl, Arthur W. Harrington and Hollister Johnson, E. K. Morse and Harold A. Thomas, Montrose W. Hayes, and W. E. R. Covell. 551. Discussion: Fred C. Scobey, Howard T. Critchlow, Theodore T. Knappen, M. C. Tyler, Gordon R. Williams, Arthur T. Safford, W. G. Hoyt, J. D. Arthur, Jr., John H. Meursinge, H. K. Barrows, E. D. Hendricks, Edward W. Bush, Ivan E. Houk, John E. Field, C. S. Jarvis, Joseph Jacobs, W. M. Dawley, Howard M. Turner, Ralph W. Powell, and Franklin F. Snyder. 665.

FLUMES.

"Measurement of Débris-Laden Stream Flow with Critical-Depth Flumes." H. G. Wilm, John S. Cotton, and H. C. Storey. (With Discussion.) 1237.

FOUNDATIONS.

"Graphical Distribution of Vertical Pressure Beneath Foundations." Donald M. Burmister. 303. Discussion: William P. Kimball, I. M. Nelidov, George Paaswell, Jacob Feld, Nathan M. Newmark, A. E. Cummings, D. P. Krynine, and A. A. Eremin. 314.

"Practical Application of Soil Mechanics": A Symposium. Spencer J. Buchanan, Stanley M. Dore, B. K. Hough, Jr., and Charles Terzaghi. (With Discussion.) 1377.

"Pressures Beneath a Spread Foundation." D. P. Krynine. (With Discussion.) 827.

"Soil Reactions in Relation to Foundations on Piles." R. M. Miller. (With Discussion.) 1193.

Stability of embankment foundations. 1414.

FREIGHT.

"Economics of the Ohio River Improvement." C. L. Hall. (With Discussion.) 1527.

FRICTION.

Skin friction between piles and soil. 1200.

GAS AND GAS-WORKS.

Data relating to gas collection, utilization, and sale at sewage treatment works. 1669, 1690.

GEODESY.

"Practical Use of Horizontal Geodetic Control." R. C. Sheldon. 791. Discussion: Philip Kissam, Ralph Z. Kirkpatrick, E. B. Roberts, H. W. Hemple, J. C. Carpenter, George D. Whitmore, R. M. Wilson, and Julius L. Speert. 803.

GEOMETRY.

"Deflections by Geometry." David B. Hall. 275. Discussion: A. J. McGaw, L. E. Grinter, Ralph W. Stewart, and William Bertwell. 288.

GRAPHICAL CHARTS.

"Solution of Transmission Problems of a Water System." Ellwood H. Aldrich. (With Discussion.) 1579.

HIGHWAYS AND ROADS.

"Effect of Dowel-Bar Misalignment Across Concrete Pavement Joints." Arthur R. Smith and Sanford W. Benham. 1133. Discussion: L. W. Teller, David J. Peery, L. J. Mensch, W. O. Fremont, George A. Smith, and L. E. Grinter. 1145.

"Essential Considerations in the Stabilization of Soil." C. A. Hogentogler and E. A. Willis. (With Discussion.) 1163.

HYDRAULIC JUMP.

Study of feasibility of using hydraulic jump for energy dissipation. 1083.

HYDRAULIC LABORATORIES.

"Construction and Testing of Hydraulic Models, Muskingum Water-Shed Project." George E. Barnes and J. G. Jobes. (With Discussion.) 227.

"Rainfall Intensities and Frequencies." A. J. Schafmayer and B. E. Grant. 344. Discussion: Victor H. Cochrane, LeRoy K. Sherman, J. O. Jones, Charles W. Sherman, Glen N. Cox, Garrett B. Drummond, Eugene L. Grant, Adolph F. Meyer, Clinton L. Bogert, C. H. Eiffert, and C. S. Jarvis. 369.

REINFORCED CONCRETE.

"Design of Reinforced Concrete in Torsion." Paul Andersen. 1503. Discussion: C. W. Deans, L. E. Grinter, Bruce G. Johnston, Dean Peabody, Jr., Walter H. Wheeler, A. Floris, E. Neil W. Lane, A. A. Eremin and Harold E. Wessman. 1512.

"Effect of Dowel-Bar Misalignment Across Concrete Pavement Joints." Arthur R. Smith and Sanford W. Benham. (With Discussion.) 1133.

"Pre-Stressed Reinforced Concrete and Its Possibilities for Bridge Construction." Ivan A. Rosov. 1334. Discussion: Charles S. Whitney, Karl W. Lemcke, Dean F. Peterson, Jr., M. Hirschthal, A. Floris, and A. A. Eremin. 1359.

REPORTS OF COMMITTEES.

"Standard Practice in Separate Sludge Digestion." Final Report of the Committee of the Sanitary Engineering Division on Sludge Digestion. Samuel A. Greeley, W. L. Havens, C. B. Hoover, C. E. Keefer, and John F. Skinner. 1662.

RESERVOIRS.

Behavior of New England storage reservoirs in floods of November, 1927, and March, 1936. 609.

Data regarding tributary discharges to Elephant Butte Reservoir, 1931 to 1936. 749.

"National Aspects of Flood Control": A Symposium. James J. Davis, Abel Wolman, Nathan B. Jacobs, W. F. Uhl, Arthur W. Harrington and Hollister Johnson, E. K. Morse and Harold A. Thomas, Montrose W. Hayes, and W. E. R. Covell. (With Discussion.) 551.

"Solution of Transmission Problems of a Water System." Ellwood H. Aldrich. (With Discussion.) 1579.

"The Passage of Turbid Water Through Lake Mead." Nathan C. Grover and Charles S. Howard. (With Discussion.) 720.

RIVERS.

Analysis of Colorado River water. 779.

"Economics of the Ohio River Improvement." C. L. Hall. 1527. Discussion: Eugene L. Grant, Fred Lavis, O. Slack Barrett, Edmund L. Daley and Forrest E. Byrns, J. E. Willoughby and W. D. Faucette, and W. E. R. Covell. 1553.

Flood control on the Mississippi River. 651.

Levees in the Lower Mississippi Valley. 1378.

"National Aspects of Flood Control": A Symposium. James J. Davis, Abel Wolman, Nathan B. Jacobs, W. F. Uhl, Arthur W. Harrington and Hollister Johnson, E. K. Morse and Harold A. Thomas, Montrose W. Hayes, and W. E. R. Covell. (With Discussion.) 551.

SEEPAGE.

"Practical Application of Soil Mechanics": A Symposium. Spencer J. Buchanan, Stanley M. Dore, B. K. Hough, Jr., and Charles Terzaghi. (With Discussion.) 1377.

"Selection of Materials for Rolled-Fill Earth Dams." Charles H. Lee. (With Discussion.) 1.

SEWAGE DISPOSAL.

"Aeration Tanks for Activated Sludge Plants." S. W. Freese. 1620. Discussion: Norval E. Anderson, and Weston Gavett. 1641.

"Standard Practice in Separate Sludge Digestion." Final Report of the Committee of the Sanitary Engineering Division on Sludge Digestion. 1662.

SILT.

Data regarding tributary discharges to Elephant Butte Reservoir, 1931 to 1936. 749.

"The Passage of Turbid Water Through Lake Mead." Nathan C. Grover and Charles S. Howard. (With Discussion.) 720.

SNOW.

Climatological data at various places in New England. 586, 587, 588.

SOILS.

"Essential Considerations in the Stabilization of Soil." C. A. Hogentogler and E. A. Willis. 1163. Discussion: Jacob Feld and Donald M. Burmister. 1184.

"Practical Application of Soil Mechanics": A Symposium. Spencer J. Buchanan, Stanley M. Dore, B. K. Hough, Jr., and Charles Terzaghi. 1377. Discussion: George E. Beggs, M. L. Enger, R. J. Fogg, Harry T. Immerman, D. P. Krynine, F. A. Marston, George Paaswell, Ralph R. Proctor, Charles Terzaghi, Lazarus White, Glennon Gilboy, S. C. Hollister, Theodore T. Knappen, L. F. Harza, Edward Adams Richardson, Richards M. Strohl, William P. Creager, Jacob Feld, Y. L. Chang, Charles Senour, Donald M. Burmister, Donald W. Taylor, Lee H. Johnson, Jr., Gregory P. Tschebotareff, William L. Wells, and A. Streiff. 1449.

" Selection of Materials for Rolled-Fill Earth Dams." Charles H. Lee. (With Discussion.) 1.

Settlement of structures in Europe and methods of observation. 1432.

" Soil Reactions in Relation to Foundations on Piles." R. M. Miller. 1193. Discussion: Hibbert M. Hill, George P. Stowitts, George A. McKay, Chandler Davis, Harry E. Sawtell, and J. Stuart Crandall. 1217.

SPILLWAYS.

" Hydraulic Tests on the Spillway of the Madden Dam." Richard R. Randolph, Jr. 1080. Discussion: Ettore Scimemi, J. C. Stevens, F. W. Edwards, and Morrough P. O'Brien. 1113.

STREAM FLOW.

" Measurement of Débris-Laden Stream Flow with Critical-Depth Flumes." H. G. Wilm, John S. Cotton, and H. C. Storey. 1237. Discussion: R. L. Parshall, Martin A. Mason, Edwin S. Fuller, Harold K. Palmer and Fred D. Bowlus, Harry F. Blaney, R. L. Stoker, and J. C. Stevens. 1254.

STRESS AND STRAIN.

" Analysis of Stresses in Subaqueous Tunnel Tubes." A. A. Eremin. (With Discussion.) 256.

" Pre-Stressed Reinforced Concrete and Its Possibilities for Bridge Construction." Ivan A. Rosov. (With Discussion.) 1334.

" Stresses Around Circular Holes in Dams and Buttresses." I. K. Silverman. (With Discussion.) 133.

Wheel load stresses. 477.

See, also, **TORSION.**

STRUCTURES, THEORY OF.

" Deflections by Geometry." David B. Hall. (With Discussion.) 275.

" Structural Analysis Based Upon Principles Pertaining to Unloaded Models." Otto Gottschalk. (With Discussion.) 1019.

SURVEYING.

" Practical Use of Horizontal Geodetic Control." R. C. Sheldon. (With Discussion.) 791.

" Readjustment of Triangulation Datum." Julius L. Speert. 1002.

TANKS.

" Aeration Tanks for Activated Sludge Plants." S. W. Freese. (With Discussion.) 1620.

" Standard Practice in Separate Sludge Digestion." Final Report of the Committee of the Sanitary Engineering Division on Sludge Digestion. 1662.

See, also, **WATER TANKS.**

TEMPERATURE.

" A New Theory of Rail Expansion." Alfred Africano. (With Discussion.) 465.

TERMINALS.

See **WATER TERMINALS.**

TIES.

" A New Theory of Rail Expansion." Alfred Africano. (With Discussion.) 465.

TORSION.

" Design of Reinforced Concrete in Torsion." Paul Andersen. (With Discussion.) 1503.

TRACK.

" A New Theory of Rail Expansion." Alfred Africano. (With Discussion.) 465.

TRADE WASTE.

Effect of various industrial wastes on sludge digestion. 1679.

TRANSPORTATION.

" Water Transportation Versus Rail Transportation ": A Symposium. Rufus W. Putnam, and S. L. Wonson. (With Discussion.) 1279.

TRIANGULATION.

" Practical Use of Horizontal Geodetic Control." R. C. Sheldon. (With Discussion.) 791.

" Readjustment of Triangulation Datum." Julius L. Speert. 1002.

TUNNEL LINING.

" Analysis of Stresses in Subaqueous Tunnel Tubes." A. A. Eremin. (With Discussion.) 256.

TUNNELS.

" Analysis of Stresses in Subaqueous Tunnel Tubes." A. A. Eremin. 256. Discussion: David J. Peery and Orrin L. Brodie. 266.

TURBULENCE.

" The Passage of Turbid Water Through Lake Mead." Nathan C. Grover and Charles S. Howard. (With Discussion.) 720.

VALUATION.

" Water Transportation Versus Rail Transportation ": A Symposium. Rufus W. Putnam, and S. L. Wonson. (With Discussion.) 1279.

VIBRATION.

" Earthquake Resistance of Elevated Water-Tanks." Arthur C. Ruge. (With Discussion.) 889.

WATER.

Analysis of Colorado River water. 779.

WATER, FLOW OF, IN OPEN CHANNELS.

"Back-Water and Drop-Down Curves for Uniform Channels." Nagaho Mononobe. 950. Discussion: J. C. Stevens, Chesley J. Posey, A. A. Kalinske, Boris A. Bakhmeteff, and P. Charles Stein. 990.

"Construction and Testing of Hydraulic Models, Muskingum Water-Shed Project." George E. Barnes and J. G. Jobes. (With Discussion.) 227.

"Measurement of Débris-Laden Stream Flow with Critical-Depth Flumes." H. G. Wilm, John S. Cotton, and H. C. Storey. (With Discussion.) 1237.

New England flood flows; 1936 peak discharges and previous maximum. 594.

"The Passage of Turbid Water Through Lake Mead." Nathan C. Grover and Charles S. Howard. (With Discussion.) 720.

WATER, FLOW OF, IN PIPES.

"Construction and Testing of Hydraulic Models, Muskingum Water-Shed Project." George E. Barnes and J. G. Jobes. (With Discussion.) 227.

"Flow Characteristics in Elbow Draft-Tubes." C. A. Mockmore. 402. Discussion: F. T. Mavis, Jerome Fee, R. E. B. Sharp, L. F. Harza, Ellery R. Fosdick, and Howard L. Cooper. 438.

"Solution of Transmission Problems of a Water System." Ellwood H. Aldrich. (With Discussion.) 1579.

WATER, FLOW OF, OVER DAMS AND WEIRS.

"Construction and Testing of Hydraulic Models, Muskingum Water-Shed Project." George E. Barnes and J. G. Jobes. (With Discussion.) 227.

"Hydraulic Tests on the Spillway of the Madden Dam." Richard R. Randolph, Jr. (With Discussion.) 1080.

"Measurement of Débris-Laden Stream Flow with Critical-Depth Flumes." H. G. Wilm, John S. Cotton, and H. C. Storey. (With Discussion.) 1237.

"The Passage of Turbid Water Through Lake Mead." Nathan C. Grover and Charles S. Howard. (With Discussion.) 720.

WATER PRESSURES.

"Solution of Transmission Problems of a Water System." Ellwood H. Aldrich. (With Discussion.) 1579.

WATER TANKS.

"Earthquake Resistance of Elevated Water-Tanks." Arthur C. Ruge. 889. Discussion: N. H. Heck, Mason A. Stone, and Franklin P. Ulrich and Dean S. Carder. 939.

WATER TERMINALS.

Terminal facilities on the Ohio River. 1491.

WATERWAYS.

"Water Transportation Versus Rail Transportation": A Symposium. Rufus W. Putnam, and S. L. Wonson. 1279. Discussion: George Hartley, W. D. Faucette and J. E. Willoughby, C. D. Bordelon, J. E. Goodrich, and H. R. Faison. 1309.

WATER-WORKS.

"Solution of Transmission Problems of a Water System." Ellwood H. Aldrich. 1579. Discussion: Lynn Perry, Charles M. Mower, Jr., Thomas R. Camp, Harold E. Babbitt, C. Maxwell Stanley, Warren E. Wilson, Harold K. Palmer, F. Knapp, and Weston Gavett. 1602.

WEIGHTS.

"Economics of Highway-Bridge Floorings of Various Unit Weights." J. A. L. Waddell. (With Discussion.) 515.

WEIRS.

AUTHOR INDEX

ADAM, ROBERT.

Memoir of. 1739.

AFRICANO, ALFRED.

" A New Theory of Rail Expansion." 465.

AIKEN, WILLIAM AUGUSTIN.

Memoir of. 1740.

ALDRICH, ELLWOOD H.

" Solution of Transmission Problems of a Water System." 1579.

ALLEN, CHARLES ROLLIN.

Memoir of. 1924.

ALLEN, WILLIAM BULLARD.

Memoir of. 1743.

ANDERSEN, PAUL.

" Design of Reinforced Concrete in Torsion." 1503.

ANDERSON, NORVAL E.

Aeration tanks. 1641.

ANDERSON, RUSSELL AVERILL.

Memoir of. 1925.

ANGUS, ROBERT W.

Economic diameter of steel penstocks. 126.

ARMSTRONG, WILLIAM DELANO.

Memoir of. 1744.

ARTHUR, J. D., JR.

Flood control. 680.

ASHBRIDGE, RICHARD I. DOWNING.

Memoir of. 1746.

ATWATER, ALBERT WORTHINGTON.

Memoir of. 1928.

BABBITT, HAROLD E.

Transmission problems of a water system. 1605.

BAKHMETEFF, BORIS A.

Back-water and drop-down curves. 997.

BALDRIDGE, C. W.

New theory of rail expansion. 480.

BARNES, GEORGE E.

"Construction and Testing of Hydraulic Models, Muskingum Water-Shed Project." 227.

BARON, FRANK M.

Open-spandrel concrete arches. 81.

BARRETT, O. SLACK.

Economics of Ohio River improvement. 1558.

BARROWS, H. K.

Economic diameter of steel penstocks. 125.
Flood control. 683.

BAUMANN, PAUL.

Rolled-fill earth dams. 20.

BECTON, JOHN LELAND.

Memoir of. 1747.

BEGGS, GEORGE E.

Application of soil mechanics. 1449.

BENHAM, SANFORD W.

"Effect of Dowel-Bar Misalignment Across Concrete Pavement Joints." 1133.

BENNETT, RALPH.

Rolled-fill earth dams. 49.

BERNARD, MERRILL.

Flood control. 715.

BERTWELL, WILLIAM.

Deflections by geometry. 297.

BETTES, CHARLES ROBERT.

Memoir of. 1748.

BIER, PETER.

Economic diameter of steel penstocks. 108.

BLANEY, HARRY F.

Débris-laden stream flow. 1266.

BLISS, JOHN H.
Turbid water through Lake Mead. 747.

BOARDMAN, H. C.
Elevated water-tanks. 943.

BOGERT, CLINTON L.
Rainfall intensities and frequencies. 392.

BONNYMAN, JAMES.
Memoir of. 1750.

BORDELON, C. D.
Water versus rail transportation. 1312.

BOWLUS, FRED D.
Débris-laden stream flow. 1264.

BRAHTZ, J. H. A.
Stresses in circular holes in dams. 153.

BRIGHTMAN, EDWIN.
Memoir of. 1957.

BRODIE, ORRIN L.
Stresses in tunnel tubes. 267.

BROSSMAN, CHARLES.
Memoir of. 1752.

BROWN, JOSEPH DUNTON.
Memoir of. 1930.

BUCHANAN, SPENCER J.
"Practical Application of Soil Mechanics: A Symposium: Levees in the Lower Mississippi Valley." 1378.

BUISSON, M. M.
Pressures beneath a spread foundation. 869.

BURMISTER, DONALD M.
Application of soil mechanics. 1476.
"Graphical Distribution of Vertical Pressure Beneath Foundations." 303.
Stabilization of soils. 1185.

BUSH, EDWARD W.
Flood control. 693.

BYRNS, FORREST E.
Economics of Ohio River improvement. 1560.

CALOR MOTA, C.
Highway-bridge floorings. 543.

CAMP, THOMAS R.
Transmission problems of a water system. 1603.

CARDER, DEAN S.
Elevated water-tanks. 945.

CARPENTER, J. C.
Horizontal geodetic control. 812.

CASLER, MELVIN DAVID.
Memoir of. 1753.

CHAMPE, GEORGE.
Memoir of. 1756.

CHANG, Y. L.
Application of soil mechanics. 1467.

CHAPMAN, ARNOLD GOODWIN.
Memoir of. 1757.

CHASE, FRANK DAVID.
Memoir of. 1759.

CHASE, JOHN CARROLL.
Memoir of. 1760.

CLEMENTS, MELVILLE FISK.
Memoir of. 1765.

COCHRANE, VICTOR H.
Rainfall intensities and frequencies. 369.

COLLINS, CLARKE PELEG.
Memoir of. 1766.

CONANT, ELBRIDGE ROBBINS.
Memoir of. 1770.

CONRAD, VERNE LOUIS.
Memoir of. 1932.

CONVERSE, FREDERICK J.
Pressures beneath a spread foundation. 874.

COOPER, HOWARD L.
Flow characteristics in elbow draft-tubes. 453.

COOPER, HUGH LINCOLN.

Memoir of. 1772.

COPE, ERLE LONG.

Memoir of. 1777.

COTTON, JOHN S.

"Measurement of Débris-Laden Stream Flow with Critical-Depth Flumes." 1237.

COVELL, W. E. R.

Economics of Ohio River improvement. 1568.
"National Aspects of Flood Control: A Symposium: Federal Plans for Flood Control." 650.

COX, GLEN N.

Rainfall intensities and frequencies. 382.

COX, JOEL B.

Rolled-fill earth dams. 28.

CRANDALL, J. STUART.

Soil reactions. 1230.

CREAGER, WILLIAM P.

Application of soil mechanics. 1462.
Rolled-fill earth dams. 37.
Turbid water through Lake Mead. 739.

CRITCHLOW, HOWARD T.

Flood control. 665.

CROSS, HARDY.

Open-spandrel concrete arches. 86.

CULYER, THURSTON CARLYLE.

Memoir of. 1778.

CUMMINGS, A. E.

Pressures beneath foundations. 324.

CUSHMAN, WILLIAM HERBERT.

Memoir of. 1781.

DALEY, EDMUND L.

Economics of Ohio River improvement. 1560.

DAVIS, CALVIN V.

"Reclamation as an Aid to Industrial and Agricultural Balance." 181.

DAVIS, CHANDLER.

Soil reactions. 1223.

DAVIS, JAMES J.

" National Aspects of Flood Control: A Symposium: Federal Responsibility for Flood Control." 553.

DAWLEY, W. M.

Flood control. 703.

DEANS, C. W.

Design of reinforced concrete in torsion. 1512.

DIGNUM, HARRY JOCELYN.

Memoir of. 1783.

DOBSON, G. C.

Turbid water through Lake Mead. 759.

DORE, STANLEY M.

" Practical Application of Soil Mechanics: A Symposium: Quabbin Dike Built by Hydraulic Fill Method." 1396.
Rolled-fill earth dams. 30.

DRUMMOND, GARRETT B.

Rainfall intensities and frequencies. 383.

ECKERSLEY, JOSEPH OSCAR.

Memoir of. 1785.

EDWARDS, F. W.

Hydraulic tests on spillway of Madden Dam. 1120.
Muskingum water-shed project. 245.

EIFFERT, C. H.

Rainfall intensities and frequencies. 393.

ENGER, M. L.

Application of soil mechanics. 1449.

EREMIN, A. A.

" Analysis of Stresses in Subaqueous Tunnel Tubes." 256.
Design of reinforced concrete in torsion. 1524.
Open-spandrel concrete arches. 83.
Pressures beneath a spread foundation. 869.
Pressures beneath foundations. 336.

Rolled-fill earth dams. 19.

KRYNINE, D. P.

Application of soil mechanics. 1449.
" Pressures Beneath a Spread Foundation." 827.
Pressures beneath foundations. 332.

LAMB, WILLIAM ALFRED.

Memoir of. 1826.

LANE, E. NEIL W.

Design of reinforced concrete in torsion. 1523.

LARMON, FRANK PERRY.

Memoir of. 1828.

LAVIS, FRED.

Economics of Ohio River improvement. 1556.

LEE, CHARLES H.

" Selection of Materials for Rolled-Fill Earth Dams." 1.

LEE, LASLEY.

Memoir of. 1830.

LEMCKE, KARL W.

Pre-stressed reinforced concrete. 1360.

LEWIN, JOSEPH D.

Economic diameter of steel penstocks. 113.

LEWIS, A. D.

Turbid water through Lake Mead. 757.

LIPARI, ATTILIO FELIX.

Memoir of. 1832.

MacALPINE, DAVID M.

Structural analysis based on unloaded models. 1057.

McCLINTOCK, MILLER.

Highway-bridge floorings. 542.

McGAW, A. J.

Deflections by geometry. 288.

McINNES, FRANK ALEXANDER.

Memoir of. 1835.

McIVER, M. E.

Industrial and agricultural balance. 214.

McKAY, GEORGE A.

Soil reactions. 1219.

MAENNER, LUDWIG THEODORE.

Memoir of. 1837.

MAGEE, G. M.

New theory of rail expansion. 503.

MARSTON, F. A.

Application of soil mechanics. 1449.

MASON, MARTIN A.

Débris-laden stream flow. 1257.

MAVIS, F. T.

Flow characteristics in elbow draft-tubes. 438.

MENSCH, L. J.

Dowel bars across pavement joints. 1148.
Structural analysis based on unloaded models. 1043.

MEURSINGE, JOHN H.

Flood control. 680.

MEYER, ADOLPH F.

Rainfall intensities and frequencies. 390.

MICKEY, JAMES DANIEL.

Memoir of. 1957.

MIDDLEBROOKS, T. A.

Pressures beneath a spread foundation. 868.

MILLER, R. M.

" Soil Reactions in Relation to Foundations on Piles." 1193.

MINDLIN, R. D.

Stresses in circular holes in dams. 149.

MOCKMORE, C. A.

" Flow Characteristics in Elbow Draft-Tubes." 402.

MOLITOR, FREDERIC.

Memoir of. 1838.

MONISH, B. H.

Turbid water through Lake Mead. 751.

MONONOBE, NAGAHO.

" Back-Water and Drop-Down Curves for Uniform Channels." 950.

MONROE, R. A.

Economic diameter of steel penstocks. 106.

MORAN, DANIEL EDWARD.

Memoir of. 1840.

MORRISON, JOSEPH S.

Memoir of. 1844.

MORROW, JAY JOHNSON.

Memoir of. 1846.

MORSE, E. K.

"National Aspects of Flood Control: A Symposium: Floods in the Upper Ohio River and Tributaries." 622.

MOWER, CHARLES M., JR.

Transmission problems of a water system. 1602.

NELIDOV, I. M.

Pressures beneath foundations. 315.

NESSLER, CHARLES WILLIAM HENRY.

Memoir of. 1943.

NEWMARK, NATHAN M.

"Interaction Between Rib and Superstructure in Concrete Arch Bridges." 62.
Pressures beneath foundations. 321.

NORLING, SVEN ALBERT.

Memoir of. 1945.

O'BRIEN, MORROUGH P.

Hydraulic tests on spillway of Madden Dam. 1122.
Turbid water through Lake Mead. 743.

O'CONNELL, THOMAS SARSFIELD.

Memoir of. 1850.

ORBISON, ROBERT VANCE.

Memoir of. 1851.

OREN, FRED BAILEY.

Memoir of. 1853.

PAASWELL, GEORGE.

Application of soil mechanics. 1449.
Pressures beneath foundations. 318.

PAGE, JOHN C.

Turbid water through Lake Mead. 745.

PALMER, HAROLD K.

Débris-laden stream flow. 1264.
Transmission problems of a water system. 1611.
Turbid water through Lake Mead. 741.

PARSHALL, R. L.

Débris-laden stream flow. 1254.

PATTON, RAYMOND STANTON.

Memoir of. 1854.

PAUL, CARROLL.

Memoir of. 1858.

PEABODY, DEAN, JR.

Design of reinforced concrete in torsion. 1520.

PEERY, DAVID J.

Dowel bars across pavement joints. 1146.
Stresses in tunnel tubes. 266.

PEGRAM, GEORGE HERNDON.

Memoir of. 1732.

PERRY, LYNN.

Transmission problems of a water system. 1602.

PETERSON, DEAN F., JR.

Pre-stressed reinforced concrete. 1361.

PILLSBURY, FRANKLIN CALHOUN.

Memoir of. 1861.

PLUMMER, FRED L.

Stresses in circular holes in dams. 172.

POLLOCK, CLARENCE DuBOIS.

Memoir of. 1863.

POSEY, CHESLEY J.

Back-water and drop-down curves. 992.
Stresses in circular holes in dams. 152.

POWELL, RALPH W.

Economic diameter of steel penstocks. 123.
Flood control. 708.
Muskingum water-shed project. 252.

PROCTOR, RALPH R.

Application of soil mechanics. 1449.
Rolled-fill earth dams. 50.
